# Summary

## **CANADA'S 2003 GREENHOUSE GAS INVENTORY**

### 2003 GHG Emission Trends

- Total GHG emissions in Canada in 2003, expressed as "CO<sub>2</sub> equivalent," (CO<sub>2</sub> eq) were 740 Mt. This represents a 3.0 percent increase over the 2002 total of 719 Mt and a 24 percent increase over the 1990 total of 596 Mt. The increase from 2002 to 2003 was primarily due to a colder than average winter, coupled with increases in electricity production, vehicle transport and mining activity. From 2002 to 2003 Canada's GDP grew 1.7 percent.
- Canada's overall GHG emissions intensity - the amount of GHG's emitted per unit of economic activity was 1.2 percent higher in 2003 than 2002. Since 1990 the economy has grown by more than 42.8 percent (based on GDP), compared to a 24 percent increase in GHG emissions resulting in an average decrease in Canada's GHG emissions intensity of 1 percent per year (see Table 1). The recent positive year-over-year change in GHG intensity is a result of total GHG's growing more than total GDP over the same period.

# Major changes from the previous National Inventory Report

Owing to changes in the United Nations Framework Convention on Climate Change (UNFCCC) reporting guidelines, carbon dioxide emissions from agricultural soils and non-CO<sub>2</sub> emissions from forest fires are now reported within the Land Use, Land-Use Change and Forestry (LULUCF) sector (previously known as Land-use Change and Forestry). Since the national inventory totals exclude the greenhouse gas emissions and removals from the (LULUCF) sector, these categories, previously included in the national totals, are now excluded. In addition, estimates for emissions from the aluminum production industry, which appear under Industrial Processes - Metal Production, have been revised, as well as the method of allocating emissions between domestic and international aviation. Taken together, these changes are the primary contributors to the revised national GHG estimates.

As a result, total GHG emissions previously reported for 1990 have been revised downward from 609<sup>1</sup> Mt to 596 Mt while emission estimates previously reported for 2002 have been revised downward from 731 Mt to 719 Mt. The overall impact of these changes is that emission growth over the period 1990-2002, previously reported to be 20.1%, is now estimated to be 20.7%.

Table 1 Annual Growth in Canada's GHG Emissions, Economy and GHG Intensity

	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003
GHG	-1.2%	2.9%	0.4%	3.5%	2.7%	2.6%	1.8%	1.0%	2.0%	3.5%	-1.1%	1.0%	3.0%

GHG Intensity	0.9%	2.0%	-1.9%	-1.2%	-0.1%	1.0%	-2.3%	-3.0%	-3.4%	-1.7%	-3.0%	-2.2%	1.2%

- Between 2002 and 2003, emissions from almost all sectors were up. Energy, Industrial Process, Solvent, Agriculture and Waste were up by 2.9 percent, 2.0 percent, 0.9 percent, 4.7 percent and 2.2 percent, respectively.
- Between 1990 and 2003, significant growth in exports of natural gas to the United States
  resulted in a dramatic increase in the emissions associated with the production and
  transportation of natural gas. In 2003, these emissions were 25.6 Mt, a 101 percent increase
  over the 1990 level of 12.7 Mt.

# Short Term Comparisons: 2002-2003 (figure 1)

Although year-to-year comparisons do not necessarily indicate a long-term trend, there are some short-term comparisons worth noting:

- On average, Canadian homes and businesses required more energy for space heating in the winter of 2003 than in the winter of 2002 due to either colder temperatures or prolonged cold spells or both. In 2003, Heating Degree Days, an indicator of the necessity for space heating due to the severity of cold weather, were up 5.2 percent when compared to 2002. This fact almost certainly had a large impact on fossil fuel consumption, including the commercial/institutional and residential sectors, where emissions rose by a sum of almost 5.5 Mt from 2002. Overall, activities related to energy production and consumption were responsible for the vast majority of the total year-to-year increase in emissions, accounting for 16.9 Mt of the 21.3 Mt increase.
- The short term growth in emissions from 2002 can be attributed to a 3.9% increase in the
  combustion emissions from Electricity and Heat Generation, a 33% increase from the
  combustion emission from Mining, a 10% and 4.2% increase in the commercial/institutional
  and residential sectors respectively.
- Road transportation as a whole showed a modest increase in greenhouse gas emissions of 2.4 percent, with a 0.8% decrease in emissions from light duty gasoline cars offsetting a 3.0% increase in those from light duty gasoline trucks including pickup trucks, SUVs and some vans. Heavy duty diesel On-Road vehicles increased 6.2% while Off-Road emissions for both gasoline and diesel fueled sources each increased 12%.

Figure 1- Short Term (2002-2003) Changes in Selected Sectors (Mt CO<sub>2</sub> eq)

# Long Term Comparisons: 1990-2003 (figure 2)

## **Sector Trends**

Between 1990 and 2003, the net increase in Canada's annual GHG emissions totaled about 144 Mt. Over the same period, emissions from the Energy Industries and Transportation sector increased by 123 Mt, accounting for most of the overall increase.

Within these two sectors, the greatest contributors to the overall increase were the 41 percent increase in emissions from the Electricity and Steam Generation sector (38.9 Mt), and a 25 percent increase from Vehicles (33.1 Mt). Petroleum Industries also contributed significantly, with a total increase in GHG emissions of almost 50 percent between 1990 and 2003. Almost all of the increase in the Petroleum Industries sector is attributable to the rapid growth in crude oil and natural gas exports to the United States over the period.

Some of the growth in these sectors was mitigated by reduced emissions from the Industrial Process sector.

# **Energy Industries**

Emissions from Energy Industries (including Fossil Fuel Industries, Electricity and Steam Generation, Mining, Fugitive releases and Combustion emissions from pipelines) rose by about 86.5 Mt between 1990 and 2003. Forty-five percent of that increase (38.9 Mt) was in Electricity and Steam Generation, a result of greater electricity demand coupled with continuing increases in the use of coal-fired generation over the period.

Fugitive releases (e.g. methane leaks from pipelines) contributed just as significantly to GHG emissions. The current estimates show an increase of 16 Mt between 1990 and 2003, a growth of about 42 percent. Most of this increase is the result of greater traffic through energy pipelines, largely due to higher crude oil and natural gas exports to the United States.

# **Transportation Sector**

Chemical Industry-Adipic Acid Production

Emissions in the Transportation sector rose by about 36.7 Mt, or 26 percent from 1990 to 2003. Of particular note in this sector is a 20.2 Mt increase in emissions from light duty gasoline trucks, reflecting the growing popularity of sport utility vehicles. Emissions from heavy-duty diesel vehicles increased 17.5 Mt over the period, indicative of greater heavy truck transport. Offsetting these increases were reductions in emissions attributed to gasoline and alternatively fueled cars of 4.5 Mt and 1.4 Mt respectively.

Notes:

<sup>1</sup>National totals exclude all GHGs from the Land Use, Land-use Change and Forestry sector. CO<sub>2</sub> from agricutural soils and non-CO<sub>2</sub> emissions from forest fires, which were previously included in national totals, are now excluded.  $^2$  CO $_2$  estimates from Cropland include about 16 Mt CO $_2$  of annual emissions due to land conversion to Cropland

Totals may not add due to rounding.

Notes previously included in national totals, are now excluded.  $^2$  CO $_2$  estimates from Cropland include about 16 Mt CO $_2$  of annual emissions due to land conversion to Cropland

Totals may not add due to rounding.

CANADA Region Year Table 2003

Sectoral Greenhouse Gas Emission Summary
