THE FUTURE COST OF HEALTH CARE IN CANADA, 2000 TO 2020

Balancing Affordability and Sustainability

333-01 Detailed Findings • By Glenn G. Brimacombe, Pedro Antunes and Jane McIntyre

HIGHLIGHTS

Public health expenditures are projected to rise from 31 per cent in 2000 to 42 per cent by 2020 as a share of total provincial and territorial government revenues.

The proportion of Canadians over the age of 55 will rise from 22 per cent of the population to 32 per cent by the year 2020.

Public health care costs will post an average annual growth of 5.2 per cent over the 2000 to 2020 period. Of this growth, 1.7 percentage points can be attributed to demographics (0.9 per cent due to the ageing population, and 0.8 per cent due to population growth). Private health care costs will increase, on average, by 5.0 per cent over the same period.

- Adjusting for inflation, public per capita spending on health care is projected to increase by 58 per cent, while public per capita spending on all other government services will increase by 17 per cent over the forecast period.

About The Conference Board of Canada

The Conference Board of Canada is an independent, not-for-profit research organization with affiliates in the United States and Europe. Our mission is to help our members anticipate and respond to the increasingly changing global economy. We do this through the development and exchange of knowledge about organizational strategies and practices, emerging economic and social trends and key public policy issues. Since 1954, the Board has been committed to researching innovative practices, designing new strategies and providing our members with the most up-to-date information, analysis and expertise to help them excel in Canada and around the world.

About the Leaders' Roundtable on Health, Health Care and Wellness

The Roundtable was established in June 2000. Its mission is to encourage a constructive dialogue on health, health care and wellness issues among principal stakeholders in the business community, health-related sectors, governments, health research organizations and other groups closely associated with Canada's health system. The mandate of the Roundtable is to take a multi-stakeholder approach over a three-year period to initiate and examine available research and explore issues and options related to the financing and structure of Canada's health system.

The Leaders' Roundtable also focuses on the important role that employers play in terms of their ongoing financial contributions through which they seek to improve the health status of their employees.

About the Business Research Group and Health Programs

Under the auspices of the Business Research Group, the Conference Board recently established health, health care and wellness as a new knowledge area. The objective is to develop the capacity to provide the public and private sectors with knowledge and insight on key issues and trends in the areas of health system funding and structure, in addition to the important relationships between employer wellness programs and their contributions to employee health.

THE FUTURE COST OF HEALTH CARE IN CANADA, 2000 TO 2020

Balancing Affordability and Sustainability

333-01 Detailed Findings • By Glenn G. Brimacombe, Pedro Antunes and Jane McIntyre

Canada's health care system is no stranger to headlines or discussion. It stood bravely in the face of fiscal retrenchment in the 1990s, and now, in the new millennium, it finds itself at the centre of an ongoing policy debate regarding the complex and connected issues of its funding and structure. In simplified form, the fundamental questions underlying this debate are: how much money is required, for what specific structural purpose is it intended, and what impact will it have on the health of Canadians?

This debate is all the more pertinent in light of the fact that Canada's population is ageing. This fact, probably more than any other, has brought The Conference Board of Canada into the discussion. Given that Canada's population will continue to grow and age over the next 20 years, the Conference Board has identified two research questions. First, what impact will Canada's ageing population have on total public and private spending on health over the next 20 years? Second, assuming that the current architecture of the health system and fiscal regime is held constant, what proportion of provincial and territorial government revenues will be allocated to health care over the next 20 years?

Clearly, questions around the relationship between ageing and future health care expenditures are important, particularly when one considers that in 2001 the proportion of those over the age of 55 is 22 per cent, and this will increase to 32 per cent by the year 2020—an increase of 10 percentage points. Furthermore, while our society continues to age, we need to have a clearer understanding of the relationship between our ageing population and public and private health care expenditures. For example, total per capita expenditures for those currently aged 55 to 64 are expected to double over the next two decades.

To meet this demand and others that will be placed upon the health care system, the Conference Board found that, as a share of total provincial and territorial government revenues, public health care expenditures in Canada will increase from 31.1 per cent in 2000 to 42.0 per cent in 2020.

To understand the context of the second research question that the Conference Board has identified, it is important to remember that, under the Constitution,

responsibility for health care rests with the provinces and territories. Thus, the study's focus is to estimate provincial and territorial government health care expenditures relative to its future public revenue stream. As a result, expenditures by municipal governments, workers' compensation boards, and federal direct government spending are excluded from the analysis. However, federal cash transfers (e.g., the Canada Health and Social Transfer) are included as a component of provincial and territorial government revenues.

This study breaks new ground. While other studies have undertaken projection analyses of future health care expenditures, and/or in relation to overall economic activity as measured by Gross Domestic Product (GDP), the Conference Board has taken the additional step of estimating how future economic growth translates into a public revenue stream for all provinces and territories.

This is an essential feature of the analysis—and it is one that no one else has explicitly addressed in the Canadian context. Framed this way, the study considers the future financial requirements for health care within an expenditure and revenue function approach. In other words, projected expenditures must be considered in relation to future public revenues.

In the aggregate, total provincial and territorial public and private health expenditures as a percentage of GDP are projected to increase from 8.7 per cent to 10.2 per cent over the forecast period. If one were to look at public health spending in relation to GDP only, one would observe that, on a national basis, public health spending as a share of GDP is expected to increase from 6.0 per cent in 2000 to 7.1 per cent in 2020. At the same time, private health spending as a share of GDP would increase from 2.7 per cent to 3.1 per cent.

On this basis alone, one could argue that future increases in health care expenditures are manageable in relation to overall economic growth. However, given the manner in which our tax system is constructed, there is no one-to-one relationship between nominal economic growth and the public revenue dollars that accrue to governments. This means that some of our tax structures, such as excise and property taxes, are not as responsive

to economic growth. In addition, an ageing population will tend to consume less and save more, reducing the government's revenue from some indirect taxes, such as retail sales taxes. As a result, the overall share of government revenues relative to GDP is expected to decline over the next 20 years. Furthermore, it is likely that there will be continued international pressure on Canada to re-examine its fiscal regime. Therefore, what may appear to be manageable in the context of overall GDP is less manageable when compared to the growth in public revenues.

This point is underscored given that provincial and territorial public health care expenditures are expected to increase by 5.2 per cent over the forecast period, and public revenues are projected to increase by 3.6 per cent from 2000 to 2010, and 3.8 per cent from 2011 to 2020.

In addition, while health care is clearly a fundamental service, other sectors in society also have a legitimate

claim on the public purse. With health care expenditures expected to rise over the next 20 years, governments will have a difficult balancing act in terms of collecting public revenues and then allocating them among competing social programs and other important public initiatives.

If the status quo is not sustainable, then the study serves to underscore the need for further research and discussion when it comes to looking at the system's structure, and how and at what level it should be financed.

Finally, it is also important to understand that the impact of a growing and ageing population washing onto the shores of the health care system will not happen overnight. In fact, it would appear that we have time to think carefully about the policy issues and develop a course of action so that we can structure the health care system to meet the objective of timely access to quality care within an affordable financial structure.

Overall Approach

Underpinning this analysis is a series of assumptions about the structure of the health care system. As a starting point, the overall delivery structure of the health care system—both public and private—is held constant, and other than tracking changes in per capita spending patterns, no changes in treatment protocols are incorporated into the model.

The health expenditure analysis is based on the historical record of changes in nominal and inflation-adjusted (i.e., real) public and private per capita health care spending for each of 18 age-sex cohorts. From this point, total public and private health expenditures are projected forward from the most recent year to 2020 based on these real per capita expenditures and the changing distribution of the population.

For the purposes of the analysis, the data are presented in both nominal (current) and real (constant) dollars. Nominal public and private health expenditures give the reader a sense of the actual dollar amounts that are projected over the next 20 years. Presented in real dollars (with 1992 as the base year), an adjustment is made to account for price inflation. As a result, changes in real public and private health expenditures capture overall movements in the level or volume of services provided.

The report also includes econometric projection analyses that focus on how future economic growth translates into public revenues. The Conference Board of Canada's National Forecasting Model provides the long-term economic outlook for Canada.

The outlook provides a forecast for GDP, personal income and corporate profits, price inflation and transfers from the federal government to provincial and territorial governments. Combined, these factors contribute to the future public revenue stream for provincial and territorial governments.

Limitations to the Analysis

The report recognizes that the world of health policy is more likely grey than black and white. As a consequence, there are limitations to this analysis. In particular, health care systems are dynamic and evolve over time. As a result, some will argue that we have overestimated future health care expenditures and some will argue the reverse.

However, a number of important policy issues that have been identified in this paper suggest that the projected cost of health care in relation to public revenues could well be a "floor," rather than a ceiling:

- No adjustment to either the cost of salaries of health care staff, or fees paid to physicians is beyond 2.2 per cent a year. If this is too modest, especially in the current period and over the next few years, then the cost will be an underestimate. However, the level of service provided will remain the same.
- There is no assumption about the expansion of public funding for home care or pharmacare programs. In other words, the "boundaries" of Medicare as we know it, in relation to private health spending, are held constant.
- There is no adjustment to the range of services that were either no longer covered or added under Medicare. This would take us into the discussion around medically necessary services and comprehensiveness. This discussion is important, given the pressures to expand coverage that will likely flow from the introduction of new technologies, such as the human genome project, diagnostics and therapeutics, and/or new reproductive technologies.
- In the next decade, we can expect an increased ability to "design" drugs for individuals. We do not know, however, how expensive this will be. We can expect that there will be public pressure to have these modalities covered under the current approach to health care. As we look at the costs of drugs, which are growing rapidly, we are reminded of the impact of technology and what can be done on the frontiers of science. Whether state-of-the-art diagnoses and treatments will be included immediately under Medicare will be debated. We made no assumptions about these types of changes.
- Net international migration (immigration and returning Canadians less emigration) will increase to 294,000 by 2020. This is important, for if immigration levels are weaker, they will have an impact on employment, income generation and tax revenues and will therefore increase the proportion of government revenues devoted to health care.
- Tax rates are held at current levels throughout the analysis. The constraint on public spending will be bound much more by what government revenues can be in the future, within the current tax regime. That being

Health care
systems are
dynamic and
evolve over
time.

said, governments are continually being pressured to lower the tax burden on Canadians—on both individuals and businesses.

- Governments continue to achieve a slight surplus over most of the forecast period and will be reluctant to return to the days of deficit financing.
- Finally, we assume no recession in the forecast. If there is an unanticipated short-term decline in economic activity and public revenues, this could have an effect on resources that are allocated to the health care system over the short-to-medium term.

Combined, these eight points reinforce the notion that we have taken a cautious approach to the question of forecasting health care expenditures and government revenues. In sum, it would appear that while we have fundamentally left the structure of the health care system and fiscal regime unchanged, quite large increases in public health expenditures as a share of government revenues will be needed.

That having been said, several factors that are not addressed in this paper could lead to a more efficient, affordable and cost-effective health care system.

- There are possibilities for further system efficiencies to be achieved in the system. While a number of

important pilot projects are underway, such as new models of delivering primary health care and the introduction of new health information technologies, we incorporated no assumptions about the financial impact of such structural changes.

- While the projections are based on the recent historical record in real per capita expenditures, we assume no quantum changes in how health care is delivered or how patients would either increase or decrease their “consumption” of health care services.
- Although it would appear that we are on the verge of reaping benefits from new technologies, we make no judgements about any net savings that would accrue to the system by virtue of their introduction.
- Finally, the analysis assumes that there are no quantum positive or negative changes in economic activity or the tax regime that could generate a significant increase or decrease in public revenues, or a reallocation of public revenues away from or to health care.

This overall approach informs this paper, which is the first of three that focus on the future financial sustainability of the health care system.

Introduction

As we edge deeper into the new millennium, Canada has a number of policy roads it may choose to follow when it comes to the future of the health care system. In contemplating which roads to take, our collective values will play a crucial role in defining "The Canadian Way."¹ This is a particularly important point when one considers that the future of Canada's health care system stands as the most important public policy challenge identified by Canadians.²

While values are an essential ingredient in the discussion, there is a larger strategic policy context that Canadians will have to consider, as well. For each additional public dollar that we choose to allocate to health care, there is one less dollar for education, social services, debt reduction and other important public initiatives, given the current fiscal regime. Although health care is clearly a fundamental service, we must also remember that other important sectors in society have a legitimate claim on the public purse.

After a decade marked largely by fiscal retrenchment of the health care system, it is now time to focus attention on the complex and connected policy issues of funding and structure. In its simplified form, the policy equation seeks to answer the following questions: how much money is required, for what specific structural purpose is it intended, and what impact will it have on the health of Canadians?

In many respects, The Conference Board of Canada has entered this policy discussion in an effort to better understand what kind of resources will be required given that Canada's population will continue to grow and age over the next 20 years. In undertaking research into this subject, the Board asked two research questions:

- What impact will Canada's ageing population have on total provincial and territorial public and private spending on health over the next 20 years?
- Assuming that the current architecture of the health system and fiscal regime remains constant, what proportion of provincial and territorial government revenues will be allocated to health care over the next 20 years?

The former concerns an important issue—the relationship between ageing and future health care expenditures. This is a particularly critical subject when one considers that, in a period of less than 20 years, the proportion of those over the age of 55—currently 22 per cent—will increase to 32 per cent by the year 2020. Furthermore,

while our society continues to age, we need to have a clearer understanding of the relationship between our ageing population and public and private health care expenditures. When one examines age-sex health care expenditure patterns, one sees that for the 55–64 age group, total per capita expenditures are approximately \$3,239 for males and \$3,222 for females. These expenditures are expected to double over the next two decades.

While the analysis is intended to provide a better understanding of the possible trends in future public and private health care expenditures, it also takes the unique and important step of placing health care expenditure growth within the context of available public revenues that accrue to governments.

This is an essential feature of the analysis and it is one that no one else has explicitly addressed in the Canadian context. Framed this way, the study considers the future health care resource requirements within an expenditure and revenue function approach.

Thus, in considering future health care expenditures, part of the study is a projection analysis. At the same time, however, in calculating how economic growth translates into future public revenues, the model also captures a number of behavioural relationships in an economic context.

When undertaking econometric-based projection analyses, the models are embedded with a series of assumptions. While the assumptions are explicit in the report, they do not allow for changes in any of the specified relationships. As a result, this report (Phase 1) should be considered as a "baseline" case.

This is the first of a three-phase study that examines the future financial sustainability of the health care system. Phase 2 of the project is intended to examine public and private health care expenditure growth over the next 20 years. However, it will focus on the impact by category of expenditure (e.g., hospitals, physicians, prescription drugs) rather than on the changing age-sex distribution and health consumption patterns of the population.

Perhaps more importantly, Phase 3 will vary a number of the assumptions contained in Phase 1 of the project. In effect, by adopting sensitivity analysis,³ this stage will consider several scenarios and their impact on health care expenditures and their relationship to public revenues.

Combined, the three phases of this report will address more than the issue of funding of the health care system. They will also consider the funding implications, should a

number of structural changes be introduced into the system.

This report is divided into five sections. Following the introduction and policy context is a section that describes the methodology used to determine the Canadian health expenditure and economic forecast. Included in this section are the data sources and a description of the model used to forecast public and private health expenditures, in addition to economic growth. Finally, the key assumptions used in the analysis are discussed.

The results of the study are presented in the next section. Initially, the discussion centres on the national long-term economic outlook to 2020. This leads to a review of the forecasted provincial and territorial government's public accounts over the same period. The section also

presents the outlook for public and private health care expenditures. A summary of the results and the study's conclusions are contained in the final section.

To complete the analysis, two appendices are attached. The first summarizes the key assumptions that were part of the economic forecast and health expenditure projection. The second includes a series of data tables containing the detailed results from the study. These tables display data on key economic indicators, public finance, demographics and public and private health expenditures.

It should be noted that this is not the first study that has been undertaken by the Conference Board in this area. It prepared a similar exercise for the provinces of British Columbia and Ontario.⁴

1 The concept of "The Canadian Way" was articulated by The Conference Board of Canada in its 1998 publication *Performance and Potential*. It reflects (1) our values and how we choose to manage social policy in health, education and social services; (2) the balance between individual and collective responsibility; and (3) the size and role of government in business and society.

2 Stephen Vail, *A Synthesis of Canadians' Values and Attitudes on the Canadian Health Care System* (Ottawa: The Conference Board of Canada, 2001).

3 Sensitivity analysis is a methodology that considers the financial impact of introducing different scenarios with certain assumptions altered.

4 Pedro Antunes, Mario Lefebvre and Jane McIntyre, *The Future Cost of Health Care in British Columbia* (Ottawa: The Conference Board of Canada, May 2000). Pedro Antunes, Graeme Clinton, Mario Lefebvre and Peter Lok, *The Future Cost of Health Care in Ontario* (Ottawa: The Conference Board of Canada, November 2000).

Policy Context

As with other Western countries, Canada faces the difficult and ongoing policy challenge of ensuring the future financial sustainability or integrity of its health care system.

While the term "sustainability" can refer to a number of structural features within the health care system (such as health human resources, technological endowment, and physical infrastructure, to name a few), many of the preferred solutions often depend on the requirement for additional funding.¹ In this regard, a number of health organizations and governments are giving deeper strategic thought to defining the parameters of financial sustainability and how it can be achieved.²

When considering the magnitude of future financial requirements for the health care system, the literature can be separated into two broad categories. The first category takes the approach of projecting future public health care expenditures in isolation.³ The second builds on this analysis by examining public health care expenditures in relation to economic growth, measured by GDP.⁴

In a simplified form, the two approaches have been undertaken in order to gain a better understanding of the fundamental question of what level of public spending will we, as a society, allocate to health care. In addition, the latter approach seeks to define the relationship between the growth of overall public expenditures and future economic growth.

The approach developed by The Conference Board of Canada builds on the recent literature by projecting future health care expenditures in relation to public revenues that accrue to provincial and territorial governments as

a product of economic growth. In this regard, given the Conference Board's econometric modelling capacity, the analysis is more detailed in terms of taking an additional step that translates economic growth into a public revenue stream for governments.

This is an important distinction due to the very nature of how public revenues respond to increases in economic growth. Specifically, given the manner in which our tax system is constructed, there is no one-to-one relationship between economic growth and the public revenue dollars that accrue to governments. Some of our taxes are not proportionately responsive to economic growth, such as excise taxes and property taxes. In addition, an ageing population will tend to consume less and save more, reducing the government's revenue from certain indirect taxes, such as retail sales taxes.

As a consequence, where future increases in public health care expenditures appear to be manageable in relation to overall economic growth, they translate into a difficult balancing act in terms of collecting public revenues and then allocating them among competing social programs.

In addition to projecting future public health expenditures, the analysis extends to projecting future private health expenditures. Combined, these two estimates provide a more complete picture with regard to future movements in total health spending and how it breaks down along public and private lines.

If the status quo is not sustainable, the study serves to underscore the need for further research and discussion when it comes to looking at the system's structure, and how and at what level it should be financed.

1 The Webster's II New Riverside University Dictionary defines sustainable as "... using a resource so that the resource is not depleted or permanently damaged ..."

Methodology

This section presents the methodology used in determining current and future provincial, territorial and private health care expenditures, and the fiscal outlook between 2000 and 2020. The first section discusses the various data that were used, along with the sources of these data. Next, the health expenditure models are presented as well as the critical assumptions used in the analysis.

The Data

Data Sources

Data were obtained from four principal sources:

- Statistics Canada;
- The Canadian Institute for Health Information (CIHI);
- Health Care System Division, Health Canada; and
- The Conference Board of Canada.

The majority of the historical data used by the Conference Board's national forecasting model comes from Statistics Canada. For this study, the Canadian Institute for Health Information (CIHI) provided total provincial and territorial public and private health care expenditures, and the Health Care System Division of Health Canada was the source of data for provincial and territorial public and private health care expenditures by age and gender cohort.¹

Statistics Canada also provided historical data on the provinces' and territories' public accounts. This was obtained from the Canadian System of Government Financial Management Statistics (FMS) databank. Finally, data from the Conference Board's national long-term forecast were used to provide the underlying economic assumptions for Canada over the next 20 years.

Data Processing

Since an important objective of this study is to examine health expenditures by age and gender cohorts, a number of transformations had to be performed on the source data. The first task was to ensure that the age and gender cohorts of the demographic data matched the age and gender cohorts of the health expenditure data from Health Canada. The next step was to allocate total public and private health expenditures supplied by CIHI using

Health Canada's data on the share of health expenditures by age and gender cohort. This resulted in a new data series representing the level of health expenditures by age and gender cohort, which was then used to obtain the per capita health expenditures for each age and gender cohort, for both public and private expenditures that were required for the analysis.

As a last step in the data-gathering process, provincial and territorial public accounts data were converted to a calendar year basis from a fiscal year basis. This was done to make the fiscal data compatible with both the model and data from other sources.

An important point in the analysis is the distinction between nominal (or current dollar) expenditures and real (or constant dollar) expenditures. Increased health care expenditures can be, in part, attributed to general price inflation. One purpose of this exercise is to identify increases in consumption due to demographic changes and real (net of inflation) increases in consumption (or the volume of health services provided). Thus, health expenditures on a per capita basis are modelled in real terms by adjusting for inflation. This is done simply by dividing current dollar expenditures by a price index, which in our case is indexed to 1992=\$1.00. As a result, real expenditures are measured in 1992 dollars. Once the forecast results are obtained, estimates of real expenditures are converted back to current dollars (simply by multiplying by the price index) for comparisons with current dollar government revenues and GDP.

Finally, the historical data on health expenditures by age and gender cohort are available only for the period from 1980 to 1999. Therefore, patterns of health expenditures by age and gender were established over this 20-year period.²

The Models

Forecasting models were built to project public and private health expenditures, provincial and territorial government revenues and other government expenditures over the next 20 years. These models use inputs from the demographic projection and the Conference Board's long-term economic outlook. The health expenditures model and the public accounts model are presented in Table 1. The health expenditures model allows us to forecast public and private health expenditures for 18 age and gender cohorts. The public accounts model allows a forecast of the overall provincial and territorial fiscal situation.

A detailed summary of the assumptions underlying the models is contained in Appendix A.

Demographic Projections Model

The Conference Board obtained projections of population by age and gender cohort from Statistics Canada. In order for Statistics Canada to develop these projections, however, assumptions regarding a number of key demographic parameters were required. These parameters include:

- International migration.** By 2020, net international migration (as mentioned in the Overall Approach section, this means immigration and returning Canadians less emigration) will help fuel the slow but steady rise in Canadian population growth. Total immigration levels are expected to rise from current levels to the top of the government's target range, which is between 200,000 and 225,000 immigrants per year by 2008. After this point, the ageing population will start to

give way to labour shortages, making it necessary to increase immigration levels. The age and sex structure for the immigrant population is in line with historical averages. International migration is forecast to rise to 294,000 by 2020.

- Birth rate.** The Natural Rate of Increase—or the number of births minus the number of deaths—is forecast to decline steadily over the long term. This is due, in part, to a gradual decline in the birth rate, which is projected to fall to 10 per 1,000 by the end of the forecast, down from 12 per 1,000 in 1997. The birth rate is largely influenced by two major factors: the number of women of child-bearing age and fertility rates.

Baby boomers—those born between 1947 and 1966—represent approximately one-third of the total Canadian population. They will greatly influence the direction that our population structure takes over the forecast period. As the boomers get older, a larger proportion of the population will be concentrated in the older age cohorts. The last of the baby boomers are now moving out of their child-bearing years. As a result, the number of women of child-bearing age will remain low throughout the medium term. Annual births have been declining since the end of the “baby-boom echo” in 1990 and are forecast to continue declining until 2005. After that point, however, the number of births will increase slowly as the “echo boomers”—the children of the baby boomers—reach their child-bearing years.

In the past, the fertility rate, defined as the average number of births that a woman will have over her lifetime, has been influenced by a host of different factors, including health, birth control, changing income levels, and education. The Conference Board predicts that income growth will be stable over the forecast period, and will therefore have little effect on fertility levels. In addition, the forecast assumes that labour force and post-secondary education levels are peaking for young women, who will be of child-bearing age in the coming years. This should help prevent further declines in the fertility rate over the forecast period.

Thus, we are assuming that the fertility rate will remain constant to the year 2020, at 1.55 children per woman. Note that this is well below the long-term replacement rate of 2.1, which represents the rate that is needed, excluding immigration, to keep the population stable.

- Death rate.** The other half of the natural rate equation—the death rate—is expected to rise in Canada over the next 20 years. The number of deaths is largely linked to three important factors: the economic well-being of Canadians, access to health care and the age structure of the population. The first two factors have greatly improved over time. Before the 1930s, life expectancy was approximately 60 years for both males

and females. Advances in medicine, combined with better nutrition and public health, have contributed to a significant increase in life expectancy. Latest estimates suggest that the average Canadian male is now expected to live 75.7 years, while the average Canadian female is expected to live 81.5 years. Mortality rates are expected to remain at historical levels throughout the forecast period.

Still, the ageing of Canada's population will lead to a steady rise in the number of deaths. It is expected that the death rate will reach 8.7 deaths per 1,000 population by 2020, up from its 2000 level of 7.3 deaths per 1,000.

The output from the population projection model is a forecast of population for Canada and the provinces and territories by age and gender cohort to the year 2020. This forecast is key to the long-term economic outlook for the provinces and territories as well as to the estimates of provincial and territorial health expenditures for the next 20 years. The overall population of Canada is expected to rise, albeit slowly, over the long term. Population growth will slow from an annual growth rate of 0.84 per cent in 2000 to 0.78 per cent by 2020. With this information, we can calculate that our population is expected to reach 35.7 million in 2020, an increase of 5 million persons over the next 20 years.

Long-Term Economic Outlook

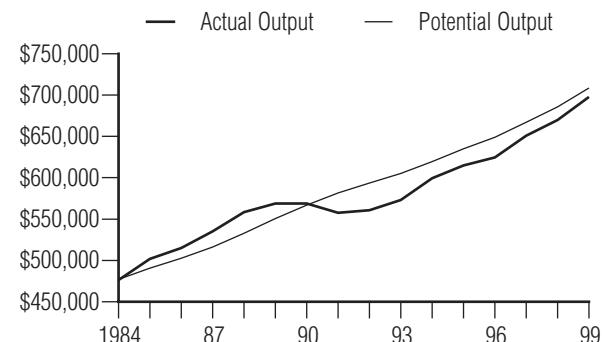

The Conference Board's National Forecasting Model provides the long-term economic outlook for Canada. There are a number of important inputs into this model, including the population forecast provided by Statistics Canada. The outlook provides us with a forecast of the components of aggregate demand (GDP), personal income and corporate profits, price inflation and transfers from the federal government to provincial and territorial governments.

In the early 1990s, the Canadian economy languished as a recession took hold. Overall real economic growth averaged only 1.5 per cent annually, more than one percentage point lower than in the previous decade. The gap between what the economy was actually producing and its potential output, often referred to as the "output gap," peaked in 1992 at 5.6 per cent.³ By 1996, this gap had narrowed to 4 per cent and the economy was starting to turn around. Real growth then averaged 3.6 per cent from 1997 to 1999, boosted by strong consumer demand and an improving fiscal situation. As a result, by 1999, the gap between potential and actual output had narrowed to 1.8 per cent (see Chart 1). The latest estimates from both The Conference Board of Canada and the Bank of Canada in its *Monetary Policy Report* suggest that this gap was fully closed by the end of 2000.⁴

Chart 1

Actual Output vs. Potential Output

(\$ 1992)

Sources: Statistics Canada; The Conference Board of Canada.

Recent estimates of potential output have been revised upwards because of information technology investment so that real GDP could expand at a strong pace over the next few years without putting upward pressure on inflation.⁵ These revisions have come about due to technological advances and the rapid growth in capital stock. After 2007, a general slowing in the rate of technological advance (as the high-tech sector matures and the pace of investment decelerates accordingly) combined with an easing of labour force growth will lead to average annual GDP growth of 2.5 per cent.

This pattern of growth will leave real GDP at its potential throughout the forecast period (see Section 3 for a more detailed description of potential output). Once the economy reaches its potential output, there are no business cycles—a common assumption for long-term economic forecasts.⁶

The Public Accounts Model

The public accounts model is used to project the combined fiscal situation of all of the provinces and territories over the next 20 years. A key assumption is that tax rates remain at current levels and reflect those incorporated in recent provincial and territorial budgets.

Government revenues have been estimated as a function of key determinants available from the Conference Board's long-term economic forecast. For instance, direct taxes are a function of personal income growth and corporate profits. Indirect taxes are based on consumer spending, while other revenues are a function of overall economic activity. The final component of government revenues, transfers from the federal government, had to be forecasted as well. Since 1996, federal cash transfers to health care, post-secondary education and social services have been allocated through the Canada Health and Social Transfer (CHST).⁷

In general, most medium-term forecasts for provincial and territorial government expenditures on goods and services are based on budget documents. However, in this study, a model was developed in order to determine a detailed long-term profile of health care expenditures (see The Health Expenditures Model section for a more detailed description). Meanwhile, the fiscal model also determines debt servicing charges and total taxpayer-supported debt because these costs have an impact on the available monies that could be allocated to health care.

In order to obtain a clear picture of public accounts, we need to provide an assumption on the level of the remaining expenditures that exclude health and debt servicing charges. In keeping with the assumption that the provincial and territorial governments' budgets are left with a slight surplus in almost every year from 2001 onwards,⁸ other expenditures (which include spending categories such as social services, education, transportation and economic development) are adjusted accordingly.

The key outputs provided by the public accounts model include:

- provincial and territorial government revenue by source;
- interest payments on the public debt;
- government balance; and
- stock of overall government debt.

The Health Expenditures Model

By using historical movements in provincial and territorial public health care expenditures by age and gender cohort, projections of per capita health expenditures have been obtained over the forecast period. Total provincial and territorial health expenditures are obtained by multiplying the population projections in each year.

All of the per capita public health care spending equations were estimated in real terms (inflation adjusted) as a function of federal cash transfers apportioned to health and a time trend variable to capture increases in per capita spending over and above inflation.⁹ The estimated trends capture both the change in the overall volume of health care services and the introduction of new technologies that lead to the provision of additional services. In principle, advances in technology should help to lower real per capita expenditures (e.g., a new drug treatment that reduces the requirement for surgery). However, in medicine, the development of new treatments for a previously untreatable condition can lead to increases in health expenditures. This is particularly true if the technology is expensive to develop and acquire.

The statistical results reveal some interesting conclusions:

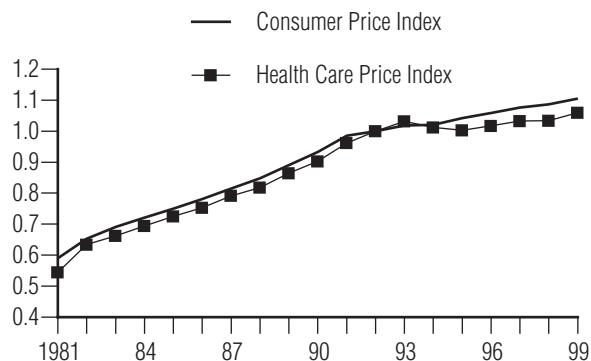

- Real per capita health care expenditures by age and gender cohort have been rising.

- The trend growth¹⁰ may be different between gender cohorts of the same age.
- The trend growth is much stronger among older cohorts (55–74).
- For the over-75 age cohorts, the trend growth falls.

For private health spending, a similar methodology was used. Per capita private health care spending equations were estimated in real terms as a function of a time trend variable to capture increases in spending over and above inflation. Again, the estimated trends capture anticipated changes in the volume of private health care services provided and increases in real consumption of health care. Once per capita private health care spending data are generated for the forecast period, these estimates are multiplied by population projections, resulting in estimates of overall private health spending.

An important component of the health expenditure model is a price index for health care spending. This index was estimated in consultation with Statistics Canada since a price index for public health expenditures does not currently exist. Public health care expenditures are composed primarily of wages and salary costs.¹¹ For this reason, a price index was created using data regarding health and social services spending on salaries, as well as employment in the health and social services fields. The price index represents the average salary in the health and social services industry.

Chart 2
Consumer Price Index versus Health Care Price Index, Canada
(1992=1.0)

Sources: Statistics Canada; The Conference Board of Canada.

History reveals that the health care price index (HPI) moves in line with the overall consumer price index (CPI). Therefore, in this analysis the HPI forecast is tied to the long-term forecast of Canada's CPI as estimated by the Conference Board in its long-term national forecast.¹² This analysis also assumes that the price deflators

are equal for both public and private expenditures. Estimates of private health care inflation are available from Statistics Canada as a component of the overall CPI. Historically, private health care inflation has not been significantly different than the constructed HPI.

This means that over the forecast period, the public-private distribution of health care expenditures

is not held explicitly constant. Rather, both sectors experienced similar rates of growth based on historical movements of the CPI, HPI and private health care inflation.

Details on the statistical history and outlook for the provincial and territorial public accounts and health expenditures are found in Appendix B.

-
- 1 Since the objective of this study is to estimate the impact of provincial and territorial governments' health care costs relative to provincial and territorial governments' revenue collection, public spending refers to that of provincial and territorial governments only. Therefore, federal government direct spending and spending by municipal governments are excluded from the total public health care spending numbers.
 - 2 Others have challenged the notion that health care expenditures must necessarily increase over time for an ageing population. See Fries, "Aging and Natural Death, and the Compression of Morbidity," *New England Journal of Medicine*, vol. 303, no. 3 (1980), pp. 130–35. R.G. Evans et al, *Apocalypse No: Population Aging and the Future of the Health Care System* (Vancouver: University of British Columbia Centre for Health Services and Policy Research, March 2001). N.G. Levinsky et al, "Influence of Age on Medicare Expenditures and Medical Care in the Last Year of Life," *Journal of the American Medical Association*, vol. 26, no. 11 (September 2001).
 - 3 In the first half of the 1990s, growth in potential output averaged 2.3 per cent annually due to the slower pace of labour force growth and lower overall capital formation. Potential output growth in the second half of the decade averaged 2.7 per cent per year as both factors recovered.
 - 4 The Bank of Canada, *Monetary Policy Report* (Ottawa: The Bank of Canada, November 2000).
 - 5 Pedro Antunes, Mario Lefebvre, Jane McIntyre and Pascal Cormier, *IT and the New Economy: The Impact of Information Technology on Productivity and Growth* (Ottawa: The Conference Board of Canada, November 2000).
 - 6 It should be noted, however, that over the long term, the introduction of one or more recessions into the forecasting scenario would not significantly alter the average growth in output over the entire forecast period. This is due to an acceleration of economic growth following a recession, which offsets the period of slower growth.
 - 7 Glenn G. Brimacombe, *The First Ministers' Accord on Health Care—Can the Discussion Move to Structure from Money?* (Ottawa: The Conference Board of Canada, May 2001).
 - 8 In the aggregate, the surplus for the provinces and territories amounts to no more than 2.3 per cent of government revenues throughout the forecast period.
 - 9 As of April 1, 1996, federal cash transfers for health, education and social services were amalgamated under the Canada Health and Social Transfer (CHST), thereby making it difficult, if not impossible, to isolate cash transfers to health. Nonetheless, a historical series was constructed tying health transfers (pre-1996) to the CHST. This series also includes federal tax points that were transferred to the provinces. The level of the constructed federal health transfers data is not as important as its changes over time, allowing the constructed series to reflect policy decisions by the federal government. This is an important explanatory variable since government reductions (or strong cash transfers) will affect the supply of health care services in a way that is not necessarily related to public demand for health services. Thus, it is assumed that adding federal government transfers into the estimations will help to determine more accurately historical patterns in the demand for health care by age and gender cohort.
 - 10 Trend growth represents the average historical rate of change of a variable.
 - 11 According to the 1998/99 Annual Hospital Survey conducted by the Canadian Institute for Health Information, 70 per cent of health care costs are allocated for wages and salaries.
 - 12 The HPI and CPI are co-integrated, thus, an error correction model was used to tie the HPI to the CPI.

Results

In order to understand the long-term outlook for health care expenditures, we first look at some of the inputs that have gone into the models. Included in this section is a description of the long-term economic outlook for Canada, followed by a discussion of the forecast for the overall fiscal position of the provinces and territories. The section is then rounded out with the presentation of the results from the model simulations of public and private health expenditures by age and gender.

Long-Term Economic Outlook

Overview

Real growth in the Canadian economy, at least until 2002, should remain relatively strong at 3.5 per cent annually.¹ This follows a period of even stronger growth, which averaged 4.2 per cent per year between 1997 and 2000, and served to close the output gap (as discussed in the previous section). This economic strength was spurred on by a significant increase in the penetration of digital technology that is unprecedented and has fundamentally altered the structure of our economy.

Take, for example, imports of office equipment. In 1994, these imports stood at \$12 billion in real terms. By 2000, they had grown to almost \$66 billion, becoming the largest component of imports. Machinery and equipment investment has also been significant: real private expenditures increased to \$91 billion, up from \$40 billion in 1994.

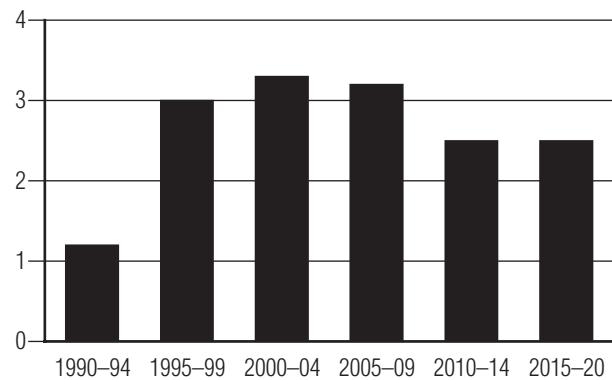

This change in the structure of the Canadian economy has implications for growth over the next 20 years. It allows for stronger potential output growth, stronger growth in labour productivity and downward pressure on the cost structure. However, there is a point at which current growth rates of machinery and equipment begin to generate absurd results. The forecast assumes that physical limits will impose a maturing of computer technology by 2008, and similarly a maturing of applications by 2014. In other words, there will come a point at which growth rates will level off. Growth in many other important categories of aggregate demand, such as consumption and investment, will return to trend levels over this period, as well.

This ageing population will contribute to slower labour force growth and lower rates of consumer spending. The slower labour force growth will keep real GDP growth in check over the latter part of the long-term forecast. This downward pressure will become most severe after 2005 as

baby boomers pass the age of 55. Consumer spending growth is expected to average 2.0 per cent annually from 2006 onwards, nearly a full percentage point lower than over the medium term. This is largely due to the fact that with a higher percentage of the population in older age cohorts, there will be less demand for new housing, and, in turn, less demand for purchases such as furniture and other durable consumer goods.

Chart 3

Real Growth in Gross Domestic Product
(average compound annual growth, percentage)

Sources: Statistics Canada; The Conference Board of Canada.

Overall, real GDP growth will therefore slow over the long term, falling from an average 3.2 per cent annually over the 2005–09 period to 2.5 per cent for the remainder of the forecast (see Chart 3).

Demographic Projection

From the assumptions set out in Section 2, three important trends emerged with respect to demographic patterns in Canada over the long term:

- The population is ageing.
- There is a slowing of the natural rate of population increase.
- There is an offsetting increase in international migration.

The final result of these trends is that Canada's population is expected to increase slowly over the long term, from an annual growth rate of 0.84 per cent in 2000 to 0.78 per cent by 2020. And, as mentioned, the result will

be that 5 million people will be added to our population over the next 20 years.

The Canadian population outlook results from the expected changes in the birth and death rates, as well as net migration flows. The natural level of population increase, defined as the excess number of births over deaths, is expected to fall sharply during the forecast period as the population ages. In 2020, this level is expected to be 52,000, which is less than one half of its current level (114,000 in the year 2000).

As mentioned earlier in the report, this change will occur for two reasons. Not only is the birth rate forecast to decline over the coming years, but also the death rate is likely to climb steadily due to the high number of baby boomers moving into the older age cohorts. In fact, by 2020, close to 25 per cent of our population will be in the 55–74 year age group (compared with 16 per cent in 2000). This will contribute to a substantial increase in the number of deaths.

The fall in the birth rate then only compounds the effects of this rising death rate. The birth rate is forecast to decline slowly for two reasons. First, the ageing population will exert downward pressure on the birth rate. Women who are currently in their child-bearing years will be past their peak fertility zone by the end of the forecast period. Since this group includes baby boomers, the group of child-bearing women that follows will be much smaller. Second, the fertility rate will remain steady at 1.55. These two factors will lower the number of births throughout the forecast period.

Net international migration will significantly contribute to population growth over the long term. By 2008, total immigration is expected to rise from its current level of approximately 200,000 per year to 225,000 per year. Increased labour shortages in the latter part of the forecast period, due to the ageing population, will make it necessary for Canada to increase immigration levels further. It is expected, therefore, that international migration will reach 294,000 people per year by 2020.

Labour Force

The ageing of the population will cause a slowdown in labour force growth for Canada over the forecast period. In the 1960s, the massive number of baby boomers entering the job market caused an explosion in labour force growth. However, this group's lower fertility rates are now contributing to the upcoming slowdown.

Participation rates² have been increasing as more women have been entering the workforce. But this trend is expected to slow over the coming years as female participation rates catch up to male participation rates. In addition, there will be a greater share of people in the higher age cohorts, which typically have lower

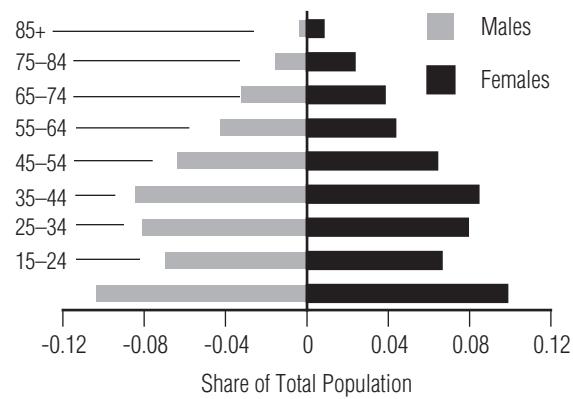

participation rates. These two factors combined will lead to a levelling off of the participation rate by the middle of this decade.

Chart 4

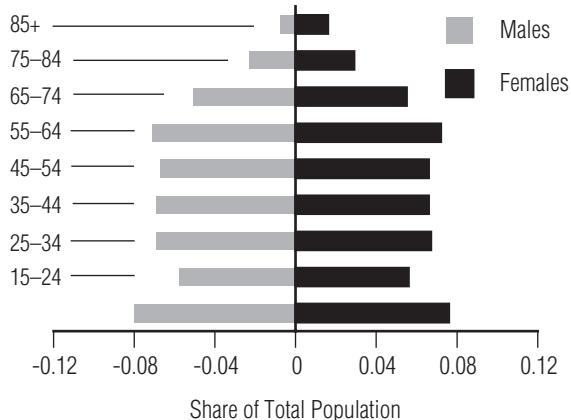

The Ageing of Canada's Population

(share of total population by age and gender cohort)

2000

2020

Sources: Statistics Canada; The Conference Board of Canada.

Thereafter, the ageing population alone could dominate the growth pattern of the overall participation rate, causing a decrease to 0.637 by 2020. However, it is assumed that labour shortages, also brought about by the ageing population, will push up real wages by 2007, thus keeping the participation rate steady at 0.655. This would lead to a stable unemployment rate over most of the long term, close to its natural rate of 5 per cent.³ However, it will not be enough to keep labour force growth steady for the forecast period. It is assumed that labour force growth will slow from 1.8 per cent per year in the current period to just 0.5 per cent annually by 2020.

Potential Output

Potential output represents the highest level of output that an economy can attain without surpassing capacity

limits and placing upward pressure on inflation. As such, it represents the measure of economic activity that can be sustained over a long period of time if all of the factors of production are fully and efficiently employed. We must remember, however, that potential output is a concept, and thus, it cannot be directly observed.

We therefore have to estimate potential output. To do so, we must assume that what an economy can produce is determined by the available labour force and the output that each worker can generate for a given capital stock. Therefore, potential output is estimated by the growth rate of the labour force and the capital stock, as well as the growth in productivity. The difference between real GDP and the potential output of an economy is often referred to as the "output gap." The recession of the early 1990s resulted in a substantial output gap for Canada.⁴ Fortunately, real growth has exceeded potential since 1992, and the gap was fully closed by the end of 2000. Future growth is now assumed to be limited to potential growth, so that inflationary pressures are not ignited. This means that the long-term growth forecast for Canada is now essentially set by the potential output growth.

The current decade is expected to see a rise in potential output growth, as the pace of high-tech investment growth continues to drive up capital stock. As mentioned earlier, this sector should reach maturity by 2008, with a resulting slowdown in the pace of capital stock investment thereafter. This factor, combined with a decline in annual labour force growth, will cause potential output growth to slow over the long term, as well. The pace of potential output growth should fall after 2005, to average just 2.5 per cent in the period from 2015 to 2020.

Fiscal Outlook

Overview

The fiscal situation in Canada today is vastly improved from that of a decade ago. Following the 1990–91 recession, total public debt reached 100 per cent of nominal GDP. This prompted all levels of government to respond with unprecedented spending reductions. As a result, by 1999 overall public spending as a share of nominal GDP had declined by more than 10 per cent from its peak of 52.4 per cent in 1992. These cuts, combined with renewed economic growth over the past few years, have resulted in a surplus situation, giving most governments some flexibility to increase spending and/or cut taxes, and/or pay down debt.

It is expected that the provinces and territories will remain in a slight surplus situation throughout the forecast period. Given this fact, debt as a share of current dollar GDP will continue to shrink. In 2000, provincial and territorial

debt represented 24.6 per cent of GDP. By 2020, this debt-to-GDP ratio will decline to 8.9 per cent. With an increasing population, provincial debt will also decline on a per capita basis, falling from \$8,284 in 2000 to \$5,972 in 2020.

Public Revenues

Provincial and territorial government revenues are composed mainly of direct and indirect taxes and transfer payments from the federal government. The taxes collected include personal and corporate income taxes, and indirect taxes such as provincial sales taxes. It is assumed for the purpose of this study that only those tax changes that have already been announced in budget documents will be included in the outlook.

The federal government provides cash transfers to the provinces and territories for several reasons, one being to assist them in financing health care services. Funds are provided through the CHST, which supports provincial programs in the areas of health, post-secondary education and social services. In September 2000, the federal government and the provinces and territories reached an agreement that would see cash transfers for health care rise sharply over the next couple of years. In specific terms, the CHST will provide to all provinces a total of \$18.3 billion in 2001–02, \$19.1 billion in the following year and then reach \$21.0 billion by 2005–06. These amounts have been incorporated into this study's forecast and are reflected in the provincial and territorial revenue estimates (see footnote 9, p.11).

The revenue growth expected from the increase in transfers over the next couple of years is being partially offset by lower tax revenues due to recently announced tax cuts in some provinces. Thus, over the next 10 years, average annual growth in total provincial and territorial government revenues will be marginally weaker than over the last decade of the forecast horizon. In current dollars, growth in total revenues will average 3.6 per cent annually between 2000 and 2010, before reaching 3.8 per cent annually between 2011 and 2020.

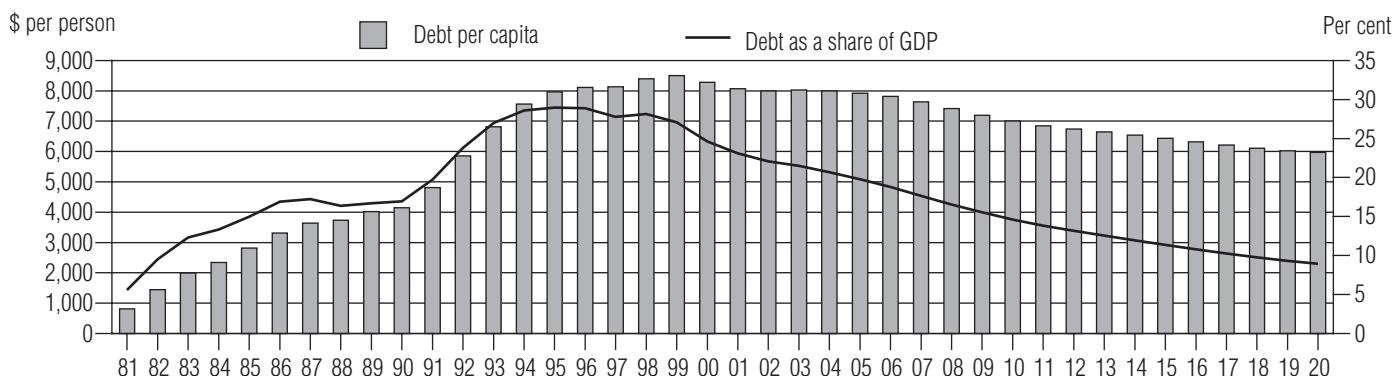

Public Expenditures

For the purposes of this forecasting exercise, provincial and territorial government expenditures have been divided into three categories:

- debt servicing charges;
- expenditures on other goods and services; and
- expenditures on health care.

Debt Servicing Charges

As mentioned previously, it is assumed that the provincial and territorial governments, already in an overall

Chart 5***Provincial/Territorial Debt: Per Capita and as a Share of Gross Domestic Product***

Sources: The Conference Board of Canada; Statistics Canada's Canadian System of Government Financial Management Statistics.

surplus situation, will maintain a slight surplus over most of the forecast period. This means that the stock of debt remains relatively flat in nominal terms over the forecast period. With interest rates held flat as well, debt charges, in current dollars, will also remain stable over the long term, thus debt charges as a share of total public expenditures are expected to fall from 14.7 per cent in 1999 to 6.2 per cent in 2020.

Expenditures on Other Goods and Services

Government expenditures on other goods and services include all monies spent by provincial and territorial governments that are not directed towards health care or servicing the public debt. This means that all provincial and territorial government expenditures on education, social services, transportation, corrections and administration are included in this expenditure category.

Expenditures on all other goods and services have been adjusted over the forecast period under the assumption of the provincial and territorial governments' slight surplus over most of the 20-year period. Thus, if health expenditures increase over the forecast period, expenditures on other goods and services are adjusted by the amount necessary to maintain this surplus.

Owing to their solid financial footing at the start of the forecast, it is expected that provincial and territorial governments will continue to have the flexibility to increase real per capita expenditures on all other goods and services, despite the increased allocation to health care.

In the aggregate, total current public expenditures on other goods and services are projected to increase from \$101.7 billion in 2000 to \$207.6 billion by 2020, with an average growth rate of 3.6 per cent over the forecast period.

In current dollar terms, expenditures on other goods and services are expected to rise from \$3,307 per person in 2000 to \$5,081 per person by 2020—an increase of 53.6 per cent. On a real per capita basis, expenditures on other goods and services are projected to increase to \$3,497 per person in 2020, up from \$2,981 per person in 2000—an increase of 17.3 per cent. Despite this increase, spending on other goods and services remains below pre 1990–91 recession levels in real per capita terms, suggesting that there have been restrictions on the level of public spending available for other goods and services.

Expenditures on Health Care

Expenditures on health care are determined by the health expenditures model and are described in Section 2. Keeping in mind that the report focuses on provincial and territorial health expenditures and revenue growth over the forecast period, expenditures by municipal governments and Workers' Compensation Boards, as well as federal government direct spending, have been excluded from the analysis. As of 2000, these categories of spending accounted for 8.3 per cent of total public spending and 4.9 per cent of total health spending in Canada.⁵

Health Expenditures Outlook

Our results show that the ageing population and the rising costs associated with it combine to increase total provincial and territorial nominal public and private health spending from \$89.5 billion in 2000 to \$243.8 billion in 2020. Of the total, 70 per cent (\$170.1 billion) comes from the public sector and the remaining 30 per cent (\$73.7 billion) from the private sector. Of note, the distribution

between the public and private sectors is expected to remain stable over the 20-year period. This reflects the similar rates of growth that each sector is expected to experience over the next two decades, rather than assuming that the current public-private distribution will remain constant.

Adjusted for inflation, total health spending is projected to increase from \$80.7 billion in 2000 to \$147.0 billion in 2020. Real provincial and territorial government health care expenditures are expected to increase from \$55.9 billion in 2000 to \$102.5 billion in 2020. This will lead to close to an approximate doubling (83 per cent) of real health care costs over the next 20 years.

This number becomes more important when one considers that, over the same time period, real growth in public expenditures on other goods and services will rise by 36.5 per cent. That is, allocations to health care outpace other expenditures by more than a 2:1 ratio. Similarly, over the same time frame, real private health spending is anticipated to increase from \$24.8 billion to \$44.5 billion—an increase of 79 per cent.

Likewise, we see that on a per capita basis, total public and private health care costs will rise as well. This is due, in part, to the fact that as people age, their health care consumption patterns become more expensive.

In 2000, total nominal per capita health expenditures stood at \$2,913—it is expected that this figure will grow to \$6,812 by 2020. Over the same period of time, public per capita spending will increase from \$2,017 to \$4,750, and private per capita spending from \$896 to \$2,062.

Adjusting for inflation, total per capita spending will increase from \$2,625 in 2000 to \$4,107 in 2020. Real public per capita health care expenditures will rise from \$1,818 in 2000 to \$2,864 in 2020, an increase of approximately \$1,000 person, or 57.5 per cent. For the same period, real private per capita health spending will increase by 54 per cent, from \$807 to \$1,243.

Trends in Public Per Capita Health Care Expenditures

The Conference Board points to at least two critical factors

that will contribute to the rise in overall provincial and territorial health care expenditures:

- the significant rise in the number of seniors; and
- more than 50 per cent of a person's lifetime health care expenditures occur after the age of 65.

These factors reflect the growth in provincial and territorial real per capita health expenditures, which averaged 1.5 per cent annually between 1982 and 2000. This compares to an expected average annual growth of 2.3 per cent over the period 2001 to 2020.

The data also reveal an interesting trend when public per capita health care costs for men and women are compared. Specifically, women account for a greater portion of health care expenditures than men in five of the nine age cohorts in 1999, and six of the nine in 2020 (see Table 2). Women's health costs tend to be greater than men's during two general periods: their child-bearing years and later in life. The greatest differences in costs tend to exist in the child-bearing period, but they are nonetheless significant after age 85 as well. Therefore, the fact that women tend to live longer than men will

Table 2
Total Nominal (Real) Public Per Capita Health Expenditures, by Age and Sex

likely contribute to increasing provincial and territorial health expenditures.

Furthermore, it is important to observe that for age cohorts from 45 to 54 onwards, nominal and real public health care expenditures for both men and women nearly double in each passing decade.

Not unexpectedly, the most important group to focus on is the baby boomers, as they constitute a large share of the overall population. Over the next 20 years, ageing baby boomers will boost the share of older age cohorts in the total population. By the end of the forecast period, baby boomers will fall between the ages of 55 and 74. Individuals over the age of 65 will make up 18.1 per cent of the Canadian population by 2020, compared to only 12.6 per cent in 2000.

The cost of treating baby boomers today (2000) is \$1,063 per person in real public terms (in 1992 dollars). At the same time, the cost of treating the current 55–74 year-old age cohort—where the baby boomers will be in 20 years—is about \$3,100. Looking ahead to 2020, we find that including technological change,⁶ but excluding inflation, the older age cohort would cost \$4,049 per person—nearly four times what each boomer costs today. If we further account for the impact of inflation, the cost of treating the baby boomers in 2020 will climb to \$6,718 per person.

Not only will the cost of treating baby boomers rise, but also there will be a rise in per capita public health expenditures over and above normal price inflation. This refers to the mix and level of health care services that are provided to an ageing population. While there can be an overall increase in the level of health services provided, there also can be the same level or volume of services, but this might be more costly to provide.

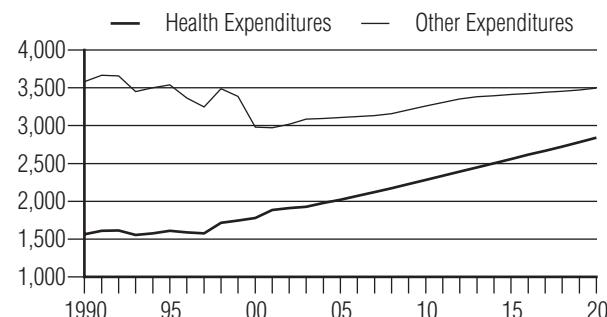

In principle, advances in technology should contribute to lowering real per capita expenditures (e.g., a new drug treatment that reduces the requirement for surgery, or new surgical techniques that reduce the length of hospital stay). However, in health care, the development of new treatments for a previously untreatable condition can lead to increases in health expenditures. This is particularly true if the technology is expensive to develop and acquire.⁷

Throughout the 1990s, moderate increases in government spending (federal, provincial and territorial) have caused provincial and territorial real per capita health expenditures to remain fairly stagnant (and even fall in some years) over the period from 1990 to 1998. That having been said, over the forecast period, a number of factors will contribute to the strong growth in real provincial and territorial health care spending, including:

- the ageing of the baby boomers;
- an increase in federal cash transfers; and
- technological progress.

This suggests that other public programs, such as education, welfare, infrastructure and administration, are not likely to receive as great a dollar share of provincial and territorial revenues as they do today. This sets the stage for considerable tension during budget debates (see Chart 6).⁸ Still, with provincial and territorial governments on their current solid footing, they are expected to be able to increase, on a real per capita basis, expenditures on other goods and services throughout the 20-year period.

Public Health Expenditures as a Share of Total Government Revenues

Canada's ageing population will certainly have an impact on public and private health expenditures over the next 20 years. And this stark fact leads us to a second issue: the growth of public expenditures in relation to future public revenues. An in-depth examination is necessary in order to help determine both the financial affordability and the long-term sustainability of provincial and territorial health care systems.

As a first step, we converted real per capita expenditures to total current dollar expenditures by accounting for demographic change and price inflation. Thus, overall public expenditures on health are expected to post an average annual growth of 5.2 per cent over the period 2001 to 2020. Of this growth, 2.1 percentage points per year can be attributed to inflation, 1.4 percentage points to real increases in the volume of services provided, and 1.7 percentage points to demographics.

The 1.7 percentage-point contribution attributed to demographic movements can be broken down in terms of two contributing factors: an ageing population (0.9 per cent), and population growth (0.8 per cent).

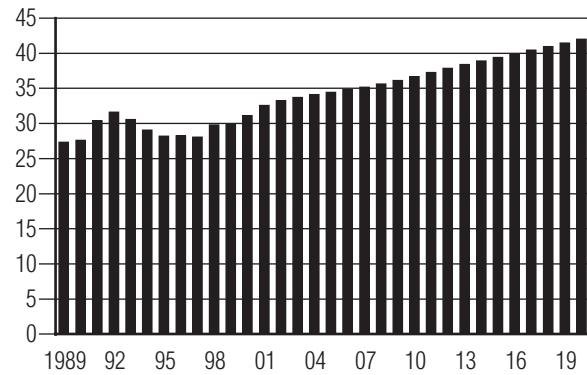

Overall expenditures on health care can be compared to total provincial and territorial revenues (both of which are measured in current dollar terms). As a share of total revenue, health expenditures are projected to increase from 31.1 per cent in 2000 to 42.0 per cent in 2020. This means that 42 cents of every tax and federal transfer dollar obtained by provincial and territorial governments will be allocated to health care in 2020.

Framed in a different context, in the aggregate, total provincial and territorial health expenditures as a percentage of GDP are projected to increase from 8.7 per cent to 10.2 per cent. If one were to look at public health spending in relation to GDP only, one would observe that on a national basis provincial and territorial, public health spending as a share of GDP is expected to increase from 6.0 per cent in 2000 to 7.1 per cent in 2020. At the same time, private health spending as a share of GDP would increase from 2.7 per cent to 3.1 per cent.

On this basis alone, one could argue that future increases in health care expenditures are manageable in relation to overall economic growth. However, given the manner in which our tax system is constructed, there is no one-to-one relationship between nominal economic growth and the public revenue dollars that accrue to governments. This means that some of our taxes, such as excise and property taxes, are not as responsive to economic growth. In addition, an ageing population will tend to consume less and save more, reducing the government's revenue stream on some indirect taxes, such as retail sales taxes. As a result, the overall share of government revenues relative to GDP is expected to decline over the next 20 years.

Therefore, what may appear to be manageable in the context of overall GDP is less manageable when compared to overall public revenues. Furthermore, while health care is clearly a fundamental service, other sectors in society also have a legitimate claim on the public purse. With health care expenditures expected to rise over the next 20 years, the government will have a difficult balancing act in terms of collecting public revenues and then allocating them among competing social programs and other important public initiatives.

Trends in Private Per Capita Health Care Expenditures

A growing and ageing population will also play a key role in contributing to private health care expenditures. Historical trends indicate that real private per capita expenditures have been rising steadily over time across most age cohorts. Once aggregated, these trend increases are not significantly different from those for the public sector. Therefore, as we move forward, the mix of public and private health care spending is not expected to change significantly, remaining at roughly 30 per cent for the private sector over the entire horizon of the 20-year forecast.⁹

The historical data do reveal some noteworthy points about private real per capita health expenditures. As with

public per capita data, trends for men and women in the same cohorts are quite similar. The data also reveal significant increases in private health care expenditures for the 65–74 and 75–84 age cohorts over the period 1992 to 2000. These increases mirror the declines witnessed in real public per capita expenditures for the same cohorts.

In the aggregate, real private per capita health expenditures were \$807 in 2000. By 2020, they are expected to reach \$1,243 per person, representing an average growth rate of 2.2 per cent over the forecast period. This growth rate is slightly lower than that estimated for per capita public expenditures (see Table 3).

-
- 1 Given the events of September 11, 2001, the Conference Board has released a revised short-term forecast.
 - 2 The participation rate (or labour force participation rate) is defined as the proportion of those employed and unemployed relative to the population aged 15 and over.
 - 3 The natural rate of unemployment is when the economy is at full-employment equilibrium; that is, there is only voluntary (as opposed to involuntary) unemployment. While short-term rates of unemployment may differ, it is the rate to which it would tend to over the long run.
 - 4 The output gap is estimated to have peaked at 5.7 per cent of potential output in 1992.
 - 5 The Canadian Institute for Health Information, *National Health Expenditure Trends, 1975–2000*, (Ottawa: The Canadian Institute for Health Information, 2000).
 - 6 This is defined as a residual of the increase in the volume of services that cannot be attributed to specific factors. While the structure of the health care system is held constant for the purposes of the analysis, it is recognized that technological innovation can have an impact on how and at what level services are provided.

- 7 The long-term trends in per capita health expenditures were estimated using statistical methods over the historical period. Results indicate that, in general, real per capita health expenditures have risen significantly due to technological change and increases in the level of access to health care.
- 8 This issue is discussed in more detail in The Conference Board of Canada's publication *Performance and Potential, 2001–02*, Chapter 6, "Canada's Fiscal Strength Allows Social Policy Choices," and Chapter 7 "Finding a Future for Canada's Health Care System."
- 9 These results are based on the assumption that there are no structural changes to the method of delivery of health care and that consumption patterns remain in line with those observed in the past.

Conclusions

While others have undertaken projections of future health care expenditures in Canada, and/or in relation to GDP, the Conference Board has taken the additional step of estimating how overall economic growth translates into a public revenue stream for all provinces. At the same time, it has also incorporated projections of private health spending into the model.

This is an essential feature of the analysis and one that no one else has explicitly addressed in the Canadian context. Framed this way, the study considers the future health care resource requirements within an expenditure and revenue function approach.

Based on its analysis, The Conference Board of Canada determined that, as a share of provincial and territorial government spending, health care expenditures in Canada are projected to increase from 31.1 per cent in 2000 to 42.0 per cent in 2020.

At the same time, the analysis shows that while real public per capita spending on health will increase from \$1,818 in 2000 to \$2,864 (an increase of 58 per cent), real public per capita spending on other goods and services will increase by approximately \$500 (or 17 per cent).

Perhaps provincial and territorial governments will feel compelled to use the savings that accrue from reduced debt servicing requirements to meet the additional demands that will be placed on the health care system by a growing and ageing population. In any case, we can expect escalating tensions between those seeking more dollars for health care versus those seeking additional resources for all the other services funded by government. This will challenge the financial sustainability of what the provincial and territorial governments currently provide, notwithstanding the possibilities of expanding public coverage under Medicare.

Not unexpectedly, a loud voice in the debate over resource allocation will be that of the baby-boom generation. Given their influence in the political arena, baby

boomers will likely be successful in demanding additional funding for health care, or they will push to have their needs met by private delivery mechanisms.

Another interesting point to keep in mind is that this report covers only the period to 2020. At that time, those at the tail end of the baby boom, who represent the largest portion of this cohort, will just be reaching their most expensive health care years. Obviously, the strains and competition for resources will not end in 2020. In fact, perhaps the biggest problems will be seen after the current forecast period ends.

Although there are defined limitations to this analysis, and no one has the ability to predict the future with complete accuracy, it appears that the projected cost of health care in Canada could well be an underestimate. Clearly, more research in this area is warranted.

It is also important to emphasize that forecasting models are built on a number of assumptions and economic relationships. This point is raised because when one undertakes projections about future public spending on health and its relationship to government revenues, the question is not necessarily one of whether the analysis is "right," but more importantly, whether it will serve to inform the policy debate and influence current behaviour.

If the status quo is not sustainable, then the study serves to underscore the need for further research and discussion when it comes to looking at the system's structure, and how and at what level it should be financed.

Finally, it is also important to understand that the impact of a growing and ageing population washing onto the shores of the health care system will not happen overnight. In fact, it would appear that we have time to think carefully about the policy issues and develop a course of action so that we can structure the health care system to meet the objective of timely access to quality care within an affordable financial structure.

Economic Assumptions

Demographic Projections

- Net international immigration levels will rise from the current range of 200,000–225,000 per year to 294,000 by 2020.
- The age and sex structure of the immigrant population is in line with recent historical averages.
- The overall fertility rate is held constant at 1.55 births per woman, and the number of births by age is held in line with recent historical averages.
- Mortality rates and their patterns are also held in line with recent historical averages.

Economic Projections

- Population growth and age/gender composition play a key role in determining potential output and consumption patterns.
- The economy will reach potential output over the next few years, and economic growth will remain in line with potential thereafter.
- With resources “fully employed,” the unemployment rate will stabilize at just over its natural rate of 5.0 per cent.

- Interest rates will remain stable over the forecast period.
- Inflation will remain in check, averaging 2.1 per cent annually over the forecast period.
- The fiscal regimes (at the federal, provincial and territorial levels) will remain unchanged from what has already been announced.
- In the aggregate, provincial and territorial budgets will maintain a slight surplus throughout the forecast period. This is done by adjusting expenditures on other government goods and services, excluding health care spending and debt servicing (which are determined within the models).

Health Expenditure Projections

- Historical patterns in real per capita increases in health care consumption (by age and gender cohort) were examined for the period 1980 to 1999. These spending patterns were maintained over the following 20-year forecast period.
- Price inflation is roughly equal across all sectors of the economy, including health care delivery in both the public and private sectors.
