## **Acknowledgements**

Thanks to representatives of the 34 central banks in this study for assisting us in compiling the data on research inputs and providing useful comments on early drafts of this paper. We would also like to thank the Governor of the Bank of Canada, David Dodge, for helping us in our communication with central banks. We benefited from comments provided by various colleagues, including Paul Corrigan, Rose Cunningham, Allan Crawford, Glenn Rudebusch, and Raphael Solomon. Thanks also to Glen Keenleyside for his editorial assistance. The complete database compiled for this study is available from the authors upon request.

---

## Abstract

The authors document the research output of 34 central banks from 1990 to 2003, and use proxies of research inputs to measure the research productivity of central banks over this period. Results are obtained with and without controlling for quality and for policy relevance. The authors find that, overall, central banks have been hiring more researchers and publishing more research since 1990, with the United States accounting for more than half of all published central bank research output, although the European Central Bank is rapidly establishing itself as an important research centre. When controlling for research quality and relevance, the authors generally find that there is no clear relationship between the size of an institution and its productivity. They also find preliminary evidence of positive correlations between the policy relevance and the scientific quality of central bank research. There is only very weak evidence of a positive correlation between the quantity of external partnerships and the productivity of researchers in central banks.

## Résumé

Les auteurs examinent les travaux publiés par 34 banques centrales de 1990 à 2003 et se servent de variables d'approximation pour mesurer la productivité de ces institutions durant la période considérée. Les résultats sont obtenus avec et sans la prise en compte de la qualité des recherches et de leur pertinence au regard des politiques publiques. Les auteurs constatent que, dans l'ensemble, les banques centrales recrutent plus de chercheurs et publient davantage de travaux depuis 1990. Plus de la moitié de toutes les études publiées sont américaines, même si l'on note que la Banque centrale européenne tend à s'imposer rapidement comme un important centre de recherche. Au chapitre de la valeur et de la pertinence des publications, les auteurs n'observent généralement aucune relation claire entre la taille d'une banque centrale et sa productivité. Des données préliminaires font toutefois apparaître une corrélation positive entre la valeur scientifique des travaux et leur pertinence sur le plan des politiques. Par ailleurs, la relation entre le nombre de partenariats externes et la productivité des chercheurs au sein des banques centrales est positive mais peu significative.

# 1. Introduction

Research is increasingly seen as critical for the success of central banks in fulfilling their mandates. It provides a strong conceptual and empirical basis for policy-making and for better communication of policies to the public. Accordingly, many central banks have invested significant resources in recent years into improving their research capabilities. At the same time, there is growing demand for accountability on the part of public agencies (including central banks) and a commitment of their managers to focus on results and to work towards strengthening performance. It is in this context that there has been increased interest in assessing central bank research output.

Jansen (1991) and Rapoport and Yi (1997) compare the publication records of the various components of the U.S. Federal Reserve System; Eijffinger, de Haan, and Koedijk (2002) and Jondeau and Pagès (2003) focus on those of central banks in Europe. Goodfriend, König, and Repullo (2004) provide a detailed assessment of the economic research activities of the European Central Bank (ECB). Dusansky and Vernon (1998) and Scott and Mitias (1996) use data on publications in scientific journals to rank university economics departments in the United States. A project recently sponsored by the European Economic Association to rank European research centres resulted in the publication of four papers (Combes and Linnemer 2003; Coupé 2003; Kalaitzidakis, Mamuneas, and Stengos 2003; Lubrano et al. 2003) in the *Journal of the European Economic Association*.

Although the details vary on the methodological approaches used to produce these papers, many share a common characteristic: they focus on publications in scientific journals as the main indicator of quality-adjusted research. Three reasons are given to justify this approach. First, there is a broad consensus among researchers that the selection criteria used by most scientific journals, particularly the use of expert anonymous referees to evaluate articles, makes publishing in these journals a good indicator of quality. Second, although it can be quite labour-intensive, measuring the number of publications in scientific journals is feasible. Indeed, it is possible to trace a researcher's publications in scientific journals using tools such as *EconLit*, the American Economic Association's electronic bibliography of economics literature throughout

the world.<sup>1</sup> Third, various rankings of scientific journals have been produced. Even if these rankings can be controversial, they make it much easier to assess the quality of scientific journals than that of other literature streams, such as working paper series or books, for which there is no widely accepted measure of quality.

Our first main contribution builds on the existing literature: we provide a systematic comparison of the research output of central banks from Western Europe, North America, Australia, New Zealand, Japan, and Israel based on publications in economic journals. To our knowledge, a systematic comparison encompassing such a large group of central banks has not yet been done. To achieve this, we built a database detailing publications by central bank researchers in all academic journals included in *EconLit*. Our database also includes various proxies for the number of researchers in central banks, including responses to questionnaires that were sent to central banks. We test the robustness of our conclusions by exploring variants of our output and input measures.

Our second main contribution is an assessment of the policy relevance of central bank publications. While we agree that publication in academic journals is a good indicator of the scientific quality of research output, to focus exclusively on journal publications has obvious limitations. In particular, it implies an excessively narrow view of the role of research in policy institutions. Central bank researchers are not exclusively paid to publish papers of interest to the academic community. They are expected to conduct research that assists policy-makers in making more informed decisions. An evaluation of research output must therefore include an assessment of the extent to which the research helps central banks conduct monetary policy, oversee the payments system, and manage foreign exchange reserves.

The management literature tells us that “What gets measured gets done” (Osborne and Gaebler 1992, 146). An exclusive focus on publications in refereed journals may bias central bank research efforts towards academic criteria and away from policy relevance. For that reason, we see a clear need to measure policy relevance, but such measurement is difficult because of the lack of good, agreed-upon data and methodology. A possible approach would be to examine in

---

<sup>1</sup> See <<http://www.econlit.org>>.

detail how specific papers published by central banks are fed into policy discussions. Goodfriend, König, and Repullo (2004) follow this approach in their evaluation of research at the ECB. However, it can be highly subjective and cannot be applied to the large number of central banks that we examine.

We propose a new approach based on the premise that having a paper cited in a publication of a policy institution is a good indicator of its usefulness for addressing policy issues. We measure policy relevance by counting the number of citations of central bank working papers in publications of the Bank for International Settlements (BIS) and the U.S. Federal Reserve System (for central banks other than the U.S. Fed). We choose these institutions because they pursue interests in practically all policy issues that are relevant to central banks. Also, the websites of these institutions are conducive to citation searches. Still, this is a very labour-intensive task. An obvious extension would be to include citations by other international policy institutions, such as the International Monetary Fund, the Organisation for Economic Co-operation and Development, or other central banks, but this would represent a considerable amount of additional work. Our efforts should be seen as a first step towards considering policy relevance in the evaluation of central bank research output.

By developing separate measures for scientific quality and policy relevance, we do not mean to imply that there necessarily is a trade-off between the two. In fact, we expect that they tend to reinforce each other. In particular, *ceteris paribus*, papers of good scientific quality are likely to be more useful for policy-makers than papers of lower quality. Also, we expect that policy relevance is an asset for publication in top journals. As another contribution to the literature, we conduct a preliminary examination of whether there is a link between the scientific quality and the policy relevance of central bank papers. Our findings in this area are consistent with our expectations.

Eijffinger, de Haan, and Koedijk (2002) find that the average product of European central banks that have a small number of researchers tends to be superior to those that have a larger number of researchers. Angelini (2003), however, argues that this result no longer holds when corrected data on the number of published papers are used, and Jondeau and Pagès (2003)

conclude that there is no significant relationship between average product and the number of researchers in Eijffinger, de Haan, and Koedijk's (2002) study. We revisit this question with our larger set of data.

Collaboration with external researchers may be an efficient way to achieve greater research productivity. In this paper, we assess the impact of these partnerships on the quantity, scientific quality, and policy relevance of central banks' research.

The rest of this paper is organized as follows. In section 2 we provide our data and explain our methodology. In section 3 we examine research output based on working papers and publications in refereed journals. In section 4 we focus on the policy relevance of central bank research. In section 5 we examine factors that can explain the quantity, quality, and policy relevance of research output. In section 6 we offer some conclusions and suggest avenues for future research.

## **2. Data and Methodology**

In this section, we provide our data on the number of researchers in central banks. We also explain how we measure research output, and how we assemble data on research input and output to produce indicators of central bank researchers' average product.

### **2.1 Measuring research inputs**

Our main measure of the number of researchers in central banks is based on responses to letters we sent the banks inquiring about the number of researchers they employed over the period 1990–2003. In our letters, we defined a researcher as an employee who performs research at least 50 per cent of the time. We defined research as work that has the potential to result in research publications such as working papers or academic journals. Most of the central banks we contacted provided the requested information, although with some difficulty in a few cases, and

some not for the entire 1990–2003 period.<sup>2</sup> We use this definition as our base-case measure of research inputs, since it reflects the self-assessments of each central bank and is based on a precise definition.

These data are shown in Table 1a of Appendix A. We observe that the number of researchers has increased in many central banks, reflecting their greater emphasis on research. Some central banks, particularly the ECB, the Deutsche Bundesbank, the Federal Reserve Bank of Chicago, and the Bank of Canada, show considerable increases over the reported period.

A limitation of this approach is that research time may be allocated differently in the various central banks. For instance, some central banks may have a few employees highly specialized in research activities. Our definition could lead to an underestimation of the number of researchers in those central banks compared with central banks where a large number of employees invest slightly more than 50 per cent of their time performing research.

To assess the robustness of our results, we consider two alternative sources of information on research capabilities. First, we consider the number of PhDs (Table 1b). These data are also compiled through our central bank survey. Second, we count the number of individuals who “revealed” themselves as researchers by authoring working papers and/or journal articles (Table 1c). This approach builds on that of Jondeau and Pagès (2003), who approximate the number of researchers in central banks by the number of authors of articles published in scientific journals. In our view, a limitation of this approach is that many researchers never publish in journals, as Combes and Linnemer (2003) discuss. The proportion of researchers who do not publish in scientific journals may vary across central banks, which could introduce biases into our comparisons. To improve on this approach, we take working papers into account. Our measure is thus based on the number of central bank employees who published at least one working paper *or* one refereed journal article in a given year (avoiding double counting). For this measure of research input, we limit ourselves to the 1999–2003

---

<sup>2</sup> Instead of using our definition, the Bank of England and the De Nederlandsche Bank found it more convenient to provide the number of researchers on a full-time equivalent basis. The Bank of Sweden provided us with the number of staff in its research department. We made no adjustment for these differences.

period. This limited sample reflects the fact that working papers are not available on the websites of many central banks for longer sample periods. These data are shown in Table 1c.

Comparing our base-case measure of the number of researchers with the alternative measures, we first find that the number of researchers is close to the number of employees with PhDs in most central banks. However, some central banks, for instance the Swiss National Bank, the U.S. Board of Governors of the Federal Reserve System, the Bank of Greece, the Bank of Sweden, and the Bank of England, have a much larger number of employees with PhDs than researchers. For these institutions, we find that the ratio of PhDs to researchers is 1.5-to-1 or more (Table 1d).

Second, we find that a few central banks have many more employees publishing papers than researchers, based on our definition. Some of these central banks, for example the U.S. Board of Governors and the Bank of England, are also part of the group that has more PhDs than researchers. However, this is not always the case. For instance, the Swiss National Bank has a relatively large ratio of PhDs to researchers, but a relatively low ratio of authors of papers to researchers.

A limitation of this second alternative is that central banks may have different publication policies. In particular, some might be more liberal than others, in that they publish a broader variety of papers (including policy or communication papers) or impose less stringent criteria for publications (section 3.1 provides evidence of this). Moreover, these policies can change through time. This approach may lead to a relative underestimation of the research capabilities of central banks that have strict publication policies.

A number of limitations to these alternative measures of research inputs are worth highlighting. The limitations of the number of employees with PhDs as a proxy for research capabilities are: (i) some institutions may ask these employees to perform activities other than research (administration, policy analysis); (ii) researchers in many central banks often do not hold PhDs; and (iii) PhDs may not be equivalent across countries. Still, we think this approach provides information that is a good complement to our measure of the number of researchers.

Also, we will use this information to determine whether having more PhD employees is correlated with more research output per researcher.

Despite some of the limitations identified above, we believe that, taken together, our three measures provide useful information about the research capabilities of central banks. Future work may consider using more precise information. For instance, it would be interesting to know how much money central banks spend on research activities. It would also be interesting to learn more about the types of PhDs employed by central banks. Unfortunately, we expect that this information would be difficult to obtain for long sample periods and for a large number of central banks.

## **2.2 Measuring research output**

We study three aspects of the research output of central banks: its quantity, its scientific quality, and its policy relevance. We use publications in scientific journals by central bank researchers and working papers published by central banks as our main sources of information on research quantity. We capture research quality by assigning weights to the published output, which are simply functions of existing quality rankings of economics journals. To assess policy relevance, we count the number of citations generated in documents published by the BIS and the U.S. Federal Reserve System.

To disseminate their research to external audiences for the purpose of either communicating new research findings or to solicit feedback from external specialists, many central banks maintain active working paper series. Unlike academic institutions, the working papers published by central banks tend to be more “polished,” in that many have gone through a formal or informal refereeing process. For this reason, compiling the number of working papers can provide a proxy for a central bank’s research output. Of course, publishing in academic journals is usually more demanding in terms of scientific quality. Accordingly, we emphasize publications in these journals as our main indicator of quality-adjusted research output.

To calculate the number of publications in academic journals, we searched the content of an extensive list of 799 journals. We require a vast list because central bankers publish their work in a wide variety of journals. Many of these journals are not included in the most “elite” list of top journals because the central bank researchers in our sample often publish in national journals that may not be included in shorter lists (Combes and Linnemer 2003). Focusing exclusively on a list of top-10 or top-20 journals, most of which are published in the United States, would be too limiting.

There are two commonly used approaches to ascribe publications to research institutions. The stock approach (used, for instance, by Combes and Linnemer 2003) counts the past production of the current employees of central banks. In contrast, the flow approach counts production at the time of publication. The stock approach is useful to assess the past publishing record of current researchers in an organization, but this is not our objective. We seek to assess the research output of central banks over time. We thus follow previous studies in this field by choosing the flow approach (Jondeau and Pagès 2003; Eijffinger, de Haan, and Koedijk 2002).<sup>3</sup>

We have constructed a database detailing publications by central bank researchers in academic journals included in *EconLit*.<sup>4</sup> Some central banks have their own publications included in *EconLit*. We exclude these from our list to avoid the obvious bias that their inclusion would imply.

Formally, we measure the research output of central banks in academic journals as follows. The journals are indexed as  $j = 1, \dots, J$ , where the total number of journals,  $J$ , equals 799. The central banks are indexed as  $k = 1, \dots, K$ , where the number of central banks considered,  $K$ , is 34. With our sample period covering the period 1990 to 2003 inclusively, the time index is  $t = 1990, \dots, T$ , where  $T = 2003$ . We can therefore denote the number of papers published in journal  $j$  by central bank  $k$  in year  $t$  as  $q_{j,k,t}$ . The sum of central bank  $k$ 's output over the whole period in all academic journals is computed as

---

<sup>3</sup> Using journal publications as a measure of research output can be imprecise, since publication policies can vary across central banks and across time.

<sup>4</sup> The search keywords used to perform searches in *EconLit* are listed in Appendix C.

$$Q_k = \sum_{t=1990}^T \sum_{j=1}^J q_{j,k,t} . \quad (1)$$

In equation (1), each journal article is given the same weight, so no consideration is given to the length of the published articles. As a robustness check, we also report results for the case where research output is defined as the sum of the number of published pages in academic journals. Denoting  $p_{j,k,t}$  as the number of published pages in journal  $j$  by central bank  $k$  in year  $t$ , the sum of published pages in all journals over the full sample is therefore

$$P_k = \sum_{t=1990}^T \sum_{j=1}^J p_{j,k,t} . \quad (2)$$

To control for differences in the quality and reputation of journals, we use the ranking proposed by Combes and Linnemer (2003).<sup>5</sup> One advantage of this ranking is that it comprises all journals listed in *EconLit*, the set of journals considered in this study. The quality-adjusted measures of published journal articles and of published pages in academic journals are, respectively,

$$\tilde{Q}_k = \sum_{t=1990}^T \sum_{j=1}^J \omega_j \times q_{j,k,t} , \text{ and} \quad (3)$$

$$\tilde{P}_k = \sum_{t=1990}^T \sum_{j=1}^J \omega_j \times p_{j,k,t} , \quad (4)$$

where the adjustment factor in equations (3) and (4),  $\omega_j$ , assumes the values 1.0, 0.67, 0.50, 0.33, 0.17, or 0.08, depending on the ranking of the journal in which the article is published. These weights are taken directly from Combes and Linnemer (2003). The complete journal list is provided in Appendix B, so  $\omega_j = 1.0$  for journals  $j = 1, \dots, 6$ ,  $\omega_j = 0.67$  for journals  $j = 7, \dots,$

---

<sup>5</sup> Another approach would be to approximate the scientific quality of a given paper by the number of times it is cited in papers published in a set of academic journals. However, this would represent a more ambitious endeavour, since the data on journal citations are difficult to obtain for a broad selection of journals. Also, the rankings that we use to weight the various journals are partly based on citations by other journals, which means that our approach already implicitly takes this consideration into account.

21, etc. For example, journals such as the *American Economic Review*, *Econometrica*, and the *Journal of Political Economy* are assigned a weight of 1.00, the *Journal of Monetary Economics* and the *Journal of Money, Credit, and Banking* are assigned a weight of 0.67, the *Journal of Banking and Finance* and the *Journal of Macroeconomics* are assigned 0.50, and *Economic Inquiry* and *Economica* are assigned 0.33. More than half of all journals are located in the bottom category and are assigned a weight of 0.08. These are usually smaller regional or specialized journals, or relatively new journals that have not yet generated sufficient citations or established a firm reputation in the discipline. To estimate the average quality of papers published by a central bank, we can simply compute the average  $\omega_j$  of its journal publications.

In robustness checks, we consider alternative sets of journal-quality weights. In particular, many central banks tend to publish in their own national scientific journals: central banks are most interested in research studies related to their national economies. Since many of the highly ranked journals in Combes and Linnemer's list are based in the United States, we consider an alternative weighting scheme in which each country's top-ranked journal is assigned a weight of 1.00.

We also propose a new approach to measure the output of policy-relevant research, based on the premise that having a paper cited in a publication of a policy institution means that an author at such an organization deemed the paper as useful in addressing a given policy issue. We measure policy relevance by counting the number of citations of central bank working papers in publications of the BIS and the U.S. Federal Reserve System.<sup>6</sup> We choose these institutions because they pursue interests in most policy issues that are relevant to central banks. Also, their websites are conducive to citation searches.

The main disadvantage of our approach is that it underestimates the number of citations of central bank work, since it does not capture citations of research papers published in journals. Ideally, we would like to count citations by the BIS and U.S. Fed of both journal articles and working papers in our construction of an indicator of policy relevance. Our decision to exclude publications in academic journals from our citation search reflects the amount of work that

---

<sup>6</sup> The search keywords used for both the BIS and the U.S. Fed websites are provided in Appendix D.

would be required to link central bank journal publications with citations in BIS and U.S. Fed documents. Fortunately, because of the often substantial lags involved in publishing in scientific journals, the BIS and U.S. Fed often cite working paper versions of a paper instead of the journal-published versions. We leave the inclusion of citations of publications other than central bank working papers for future work.

Our study includes basically all BIS publications, by both BIS staff and external contributors. For instance, research papers presented at BIS conferences by central bank economists and published in conference papers and proceedings are included. The vast majority of the latter are from central banks. Our approach thus takes into account both the opinions of BIS staff and those of staff from other central banks. Self-citations (i.e., citations of a central bank's own work by staff of that central bank) are excluded to avoid the bias this would imply.

To measure output per researcher, we simply divide the output statistics (1) through (4) by our proxies for the number of researchers in a central bank. We let  $n_{k,t}$  denote the number of researchers at central bank  $k$  in year  $t$ , and  $N_k$  denote the sum of researchers over the full sample. For example, the average annual number of journal publications per researcher at central bank  $k$  over the full sample is computed as

$$\frac{Q_k}{N_k} = \sum_{t=1990}^T \left( \frac{\sum_{j=1}^J q_{j,k,t}}{n_{k,t}} \right). \quad (5)$$

We also consider the number of working papers published by central banks as an alternative measure of research output. Although working papers are subject to fewer quality controls than papers published in academic journals, central banks usually have internal quality controls to ensure that their working papers conform to minimum quality standards. Also, the

total output of working papers may be a useful leading indicator of forthcoming publications in journals, contributing to the analysis of recent trends in the research output of central banks.<sup>7</sup>

A factor that may influence research output is the amount of collaboration with external researchers. Central bank researchers may not be as heterogeneous as their academic colleagues, so collaboration with them may be an efficient way to achieve greater research productivity. Accordingly, we assess the impact of these external partnerships on the quantity, scientific quality, and policy relevance of the research produced by central banks. To achieve this, we track the contributions of external collaborators to working papers and journal publications in order to ascertain which institutions use external contributors more intensively.

### **3. Research Output**

As noted in the introduction, research is conducted by central banks largely to assist policy-makers make better-informed decisions. Since the targeted audience for some research papers is internal, and therefore some papers are never distributed outside of the institution, it is impossible to precisely measure the complete body of research produced within central banks. For this reason, we must use publicly available research output proxies to measure the output of central banks. Nevertheless, researchers at central banks and other institutions recognize the importance of distributing research papers outside their walls, to inform the public about the work being conducted, stimulate discussions on policy-relevant issues, and, in the case of working papers, announce new research findings and solicit feedback from outside experts.

In this section, we examine the research output of central banks using the two most common publicly available measures: working papers and journal publications. For the latter, we also consider quality-adjusted measures based on the quality of the journal. In addition, we provide data on the number of journal publications per researcher in central banks.

---

<sup>7</sup> In the cases of the Bank of Japan, the Bank of Greece, and the Bank of Israel, we include only working papers published in English. This clearly implies a significant underestimation of the number of working papers published by these central banks, given that many are published in Japanese, Greek, and Hebrew. It is not feasible for us to conduct searches for documents that are published with non-Latin characters.

### 3.1 Working papers

Table 2 of Appendix A lists the number of working papers published by each central bank between the years 1999 through 2003.<sup>8</sup> We find that the Board of Governors of the Federal Reserve System (henceforth BoG) averages over 90 working papers per year, which leads all other central banks. The ECB is second in this category, despite the fact that it began operation only in January 1999. Its standing reflects the significant rise in its research output in the past three years, which coincides with the hiring of more research economists and the implementation of clear research agendas. Tied for third place are the De Nederlandsche Bank and the Bank of Finland, relatively small institutions, which have both published, on average, 44.6 working papers per year.

Following the three leaders are several institutions that publish, on average, 30 to 40 working papers per year. These include the central banks of Japan and Canada, as well as the Federal Reserve Banks of Chicago, St. Louis, and Atlanta.

As a whole, central banks have been increasing their output of working papers every year. Although the ECB accounts for a large proportion of the increase in total central bank working papers, its exclusion still leads to a notable increase in research output. The total output of working papers increased by 50 per cent between 1999 and 2003 for all central banks, and by 35 per cent when we exclude the ECB. This clearly demonstrates that central banks have been conducting more research, and will likely be reflected in more journal publications for central bankers in the coming years if working papers can be viewed as a leading indicator of such publications. Along with the ECB, central banks that have demonstrated notable upward trends (i.e., an average increase of more than four working papers per year) in the number of working papers published over this period include the central banks of the Netherlands, Canada, Finland, and England, as well as the Federal Reserve Banks of Atlanta, St. Louis, and Philadelphia. The only statistically significant negative trend is detected for the Riksbank, whose working paper output has been falling by about three per year.

---

<sup>8</sup> The list of working papers was retrieved from the websites of central banks. The working paper series considered for each central bank are identified in Appendix E.

One factor that may influence working paper output is the prevalence of external authors in a central bank's working paper series. In many instances, these external authors are short-term visitors at the central bank, and in others they co-author working papers with central bank researchers. Co-authorship of research papers is quite prevalent in the economics community, since the degree of specialization required to make original contributions to the field often calls for the collaborative efforts of researchers with complementary areas of expertise. Central bank researchers may not be as heterogeneous as their academic colleagues, so collaboration with external researchers may be an efficient way to achieve greater research productivity and gain fresh ideas.

Table 3 of Appendix A reports the percentages of external collaboration in each institution's working paper series. These percentages are computed by assigning weights to the contributions of external authors, with a paper receiving a weight of 0 if it has no external authors, 1 if it was written solely by external authors, or  $e/(c+e)$  if co-authored between central bank and external researchers, with  $c$  representing the number of "in-house" central bank researchers co-authoring a paper and  $e$  representing the number of external authors. For example, if the authorship of a working paper consists of two central bank authors and one external collaborator, then the weight assigned to the external collaborator's contribution would be 0.33, or 33 per cent.

By summing the weights assigned to the contributions of external authors over all papers published in each institution's working paper series between 1999 and 2003, we derive the aggregate percentage of external authorship (column 1 of Table 3). In the cases of the central banks of Austria, Belgium, and Switzerland, we find that the contributions of external researchers to the authorship of all working papers is more than 50 per cent, indicating that researchers at these institutions either collaborate with external researchers a great deal, or that many external economists publish the results of their research in the working paper series of these central banks. To determine whether the former or latter explanation is more pertinent, in the second column of Table 3 we list the percentage of papers that have been published in each institution's working paper series that have been solely authored by external researchers, without the collaboration of central bank economists. We find marked differences between many central

banks: some have very high percentages and some have percentages of zero. For eight central banks (the Bank of Japan and seven European institutions), more than 22 per cent of their working papers have been written by external authors. For the remaining 25 central banks, the number is below 13 per cent. These differences may reflect different uses of the central bank working paper series; the central banks of some countries may be more open to publishing the papers of external authors if the papers pertain to domestic economic issues and if alternative publication outlets are not readily available.

The third column of Table 3 lists the percentage contribution of external authors to working papers that have at least one central bank author. Based on this measure, researchers at the Danmarks Nationalbank have collaborated the most with external researchers: 45 per cent of the papers published by its staff were co-authored with external researchers. However, this percentage is computed using a relatively small sample (11 working papers); among the institutions with more active working paper series, the measure of collaboration is 41 per cent at the Atlanta Fed and 38 per cent at the Cleveland Fed. The prevalence of co-authorship is relatively high in the United States as a whole compared with other central banks, ranging from 20 per cent (at the BoG) to 28 per cent (at the San Francisco Fed) for the remaining U.S. institutions, but comprising only 5 per cent at the Bank of Japan, 7 per cent at the Australia and New Zealand Reserve Banks, 10 per cent at the Bank of Canada, and 12 per cent at the Bank of England.

### **3.2 Journal articles**

Table 4 of Appendix A lists the contribution of external co-authors to central bank publications in academic journals. Over the 1990–2003 sample, we find that Atlanta Fed researchers collaborated with external co-authors relatively more than researchers from other central banks. Indeed, 36 per cent of published papers associated with the Atlanta Fed can be attributed to researchers who are not employed by that institution, but who have collaborated with Atlanta Fed researchers. In the more recent 1999–2003 period, collaboration percentages are greatest for the National Bank of Belgium and the Federal Reserve Banks of Kansas City, Dallas, and Atlanta.

It is difficult to detect any significant trend as to whether collaboration with external authors has been increasing in recent years. In 2003, between 27 and 30 per cent of authors of papers associated with central banks were external, which is somewhat higher than the 23 per cent figure for 1993 and 1994 (data available but not reported in the tables). At this point, however, we have too few observations to deduce whether external collaboration has been increasing recently.

Table 5a of Appendix A lists the total number of journal articles published by central banks from 1990 to 2003 and for the period 1999–2003. We find that the BoG is first in total output, with 920 publications, or an average of 66 per year. The New York Fed is a distant second, with a little fewer than 23 publications per year, followed closely by the Banca d'Italia and the Minneapolis Fed. Several institutions average between 10 and 16 publications per year, including several Federal Reserve Banks (Chicago, Dallas, Atlanta, Cleveland, Philadelphia, and San Francisco) and the central banks of England, Spain, and France. To put the BoG's output into perspective, it alone accounts for 19 per cent of the publications of these 34 central banks since 1990, and as a whole the U.S. Federal Reserve System accounts for 60 per cent of all central bank publications since 1990.

In total, these 34 institutions have published more than 4,800 articles over a period in which 456,802 papers have been indexed in *EconLit*, indicating that central banks are responsible for about 1 per cent of the total new body of knowledge in economics over the past 14 years. Considering that there are thousands of academic institutions and other research centres that contribute research to the field, such output is non-negligible. We further note that there has been a strong upward trend in published central bank research, especially between 1990 and 1998, a period in which the total of all central bank publications nearly doubled, increasing from 201 to 398. Published output remained strong from 1999 to 2003, averaging 433 articles per year, with a high of 477 in 2001. By institution, the most pronounced upward trends are detected for the New York Fed and Banca d'Italia over the whole sample. For the 1999–2003 period,

significant upward trends have been detected for the ECB, Deutsche Bundesbank, and De Nederlandsche Bank.<sup>9</sup>

As stated in section 2, not all publication outlets are perceived as being of similar quality; those that have more rigorous selection processes are deemed to be of superior quality. For this reason, in Appendix B we adjust the raw published output by a quality index that is constructed using the ranking of academic journals discussed in section 2.

Table 5b of Appendix A lists the average article quality index for each institution. We find that, at 0.67, the Minneapolis Fed has the highest quality index, followed by the Richmond Fed at 0.50 and the Boston Fed at 0.49. Most other members of the U.S. Federal Reserve have a quality index above 0.40. Among other international institutions, Israel and Portugal have the highest quality indexes at 0.40. Using this index, quality-weighted production measures can be produced by multiplying the quality index by: (i) the total article count (Table 5b), (ii) the article count adjusted for the contribution of co-authors (Table 5c), and (iii) the total page count adjusted for the contribution of co-authors (Table 5d). These quality adjustments tend to be advantageous to the rankings of the U.S. institutions: the BoG and the Minneapolis, New York, and Chicago Federal Reserve Banks occupy the first four positions, respectively, using any of these three quality-adjusted measures, and for either of the 1990–2003 or 1999–2003 periods. The Bank of England, the Banca d’Italia, and the ECB are the sole non-American representatives among the top 10 central banks in quality-adjusted output.

With few exceptions, the quality-adjusted rankings in Tables 5b through d are fairly similar; most institutions do not rise or fall by more than one or two positions. However, these institutional rankings are a function of the weights assigned to the journals. Since most of the top-ranked journals are U.S.-based, this may induce a bias in favour of the U.S. institutions. Central banks that produce research papers using data on their own country may face more significant hurdles in trying to publish their work in U.S.-based journals. For example, the *Economic Record* may be the most appropriate outlet for research produced by the Reserve Bank

---

<sup>9</sup> Gaspar and Vega (2002) discuss the hypothesis that the creation of the ECB stimulated research in the Eurosystem.

of Australia, but the lower quality weighting applied to this journal may penalize Australian researchers who publish in their national journal.

To determine whether this possible U.S. bias seriously affects our results, we perform the following robustness checks. First, for each country in our sample, we identify the national journal ranked highest by Combes and Linnemer (2003). In cases where this approach leads to two or more national journals sharing first place, we pick the journal where central bank researchers from that country publish the largest number of papers. We then assign the highest possible ranking to those national journals.<sup>10</sup> This means, for instance, that the *Canadian Journal of Economics* is ranked equal with the *American Economic Review* in this robustness exercise. Table 5e of Appendix A shows the ranking of central banks based on this approach.

The ranking of central banks is not much affected by this change, with two exceptions. First, assuming that the *Spanish Economic Review* has the same quality as the *American Economic Review* implies that the ranking of the Bank of Spain improves significantly. Second, the ranking of the De Nederlandsche Bank is significantly improved by assuming that *De Economist* is a top-ranking journal.

When considering the 1999–2003 period to account for the creation of the ECB (Table 5a), we find that the ECB ranks fourth in raw publications with 141, behind the Banca d'Italia and ahead of the Chicago Fed. Having a quality index of 0.25, the ECB enters the top 15 at sixth place when quality adjustments are made for the number of co-authors and pages, and it is in seventh place when the index is applied simply to the raw article count.

Our results concerning the number of publications by European central banks are similar to those reported by Jondeau and Pagès (2003). For instance, according to Jondeau and Pagès, the four best central banks based on the unadjusted total number of *EconLit* publications are

---

<sup>10</sup> The journals that were assigned a “national weight” are as follows: *Annales d'Economie et de Statistique*, *Canadian Journal of Economics*, *De Economist*, *Economia* (Portuguese Catholic University), *Economic and Social Review*, *Economic Record*, *Ekonomiska Samfundets Tidskrift*, *Greek Economic Review*, *Investigaciones Economicas*, *Jahrbucher fur Nationalökonomie und Statistik*, *Kyklos*, *Nationaløkonomisk Tidsskrift*, *New Zealand Economic Papers*, *Politica Economica*, *Swedish Economic Policy Review*, *Tijdschrift voor Economie en Management*, *Weltwirtschaftliches Archiv/Review of World Economics*, and *Zeitschrift fur Betriebswirtschaft*.

(from first to fourth place): the Bank of Italy, the Bank of England, the Bank of France, and the Bank of Spain. Our ranking is the same, except that the Bank of France is fourth and the Bank of Spain is third. This discrepancy could be explained by the fact that Jondeau and Pagès's sample covers 1990–2002, while ours covers 1990–2003.

### **3.3 Journal publications per researcher**

Table 6a lists our data based on the average number of journal articles published per researcher in each of the central banks over the period 1999–2003. Two cases are shown: one based on our unadjusted output data and another based on our output data adjusted for the number of co-authors and the quality of journals. The number of researchers in each central bank corresponds to the number of employees who spend at least 50 per cent of their time performing research. We emphasize the 1999–2003 period because data are missing on the number of researchers in some central banks for a longer sample period (particularly for the ECB, whose activities began in 1999).<sup>11</sup>

It is interesting to note that the ranking based on the unadjusted number of articles published shows similarities with the ranking in Table 5a. In particular, most U.S. Fed banks, the ECB, the Bank of England, and the Bank of Spain rank relatively highly in both tables. Still, marked differences can be noted concerning smaller central banks, such as the Bank of Greece, the Schweizerische Nationalbank, and the Danmarks Nationalbank. These are much better ranked when average output per researcher is considered, instead of total output. On the contrary, the Federal Reserve Bank of New York, the Bank of Italy, and the Federal Reserve Bank of Atlanta rank lower when output per researcher is used, instead of total output.

The Federal Reserve Bank of Minneapolis leads the ranking based on adjusted data. In general, adjusting for journal quality tends to push U.S. institutions higher in the rankings.

---

<sup>11</sup> Other productivity rankings done by the authors reveal that focusing on the number of pages published or not adjusting for the number of co-authors lead to the same conclusions.

Table 6b shows that our results based on the adjusted number of articles published change when the number of PhDs or the number of authors of papers are used to approximate research inputs, instead of the number of researchers based on our definition. Not surprisingly, central banks that have a high ratio of PhDs to researchers in Table 1d, particularly the BoG, the Bank of Greece, the Bank of England, and the Bank of Sweden, rank much lower when the number of PhDs is used as a proxy for the number of researchers. Central banks from Ireland, France, and Australia rank much higher. The Swiss National Bank and the Boston Fed rank much better when the number of authors is used to approximate the number of researchers.

## **4. Policy Relevance**

In this section, we provide our data on the policy relevance of research based on citations in BIS documents and citations in U.S. Federal Reserve System documents.

Table 7a in Appendix A reports the results of our BIS citation search. We have compiled 890 citations over the period 1999 to 2003. This ranking is constructed based solely on the citations from central bank internal publications—working papers or proprietary policy documents such as monetary policy reports or economic reviews. They therefore do not comprise the publications of central bank economists in academic journals. As a result, it is of particular interest to compare rankings based on citations at the BIS with the one based on raw working paper output in Table 2.

Relative to their output of working papers, a number of central banks are cited disproportionately more, and others disproportionately less. Among the central banks that have increased by more than 10 positions relative to Table 2 are the Boston Fed, the New York Fed, and the Reserve Bank of New Zealand. Notable downward movements are observed for the De Nederlandsche Bank, the Bank of Finland, and the Bank of Italy.

Since the number of citations in BIS publications is one of our main measures for policy relevance of central banks' research output, and because the number of publications in journals is our main gauge of the scientific quality of that output, it is also interesting to compare rankings

based on citations with rankings based on publications in journals. For this we use the ranking based on journal publications (adjusted for quality and number of co-authors) shown in Table 5c. Central banks showing a marked improvement in the citation-based ranking are the Bank of Japan, the Reserve Bank of Australia, and the Reserve Bank of New Zealand. The Bank of Canada is an interesting case, with a high ranking both in terms of working papers published and the number of citations in BIS publications, but a much lower ranking in terms of journal publications. The Federal Reserve Bank of Minneapolis shows the opposite, with a high ranking for the number of publications but much lower rankings both in terms of the number of working papers and the number of citations. Nevertheless, many central banks, including the ECB, the Bank of England, and most U.S. Feds, are highly ranked both in terms of journal publications and citations in BIS publications.

Table 7b shows the number of citations divided by the number of researchers in central banks (based on the 50 per cent plus definition). The rankings of some central banks improve markedly by this measure in comparison with those based on the number of journal publications per researcher (Table 6a). This is particularly the case for the Reserve Bank of New Zealand and the Reserve Bank of Australia. As before, many of the central banks with a high ranking by one measure also rank highly by the other measure.<sup>12</sup>

The central banks of Australia, Ireland, Japan, and the United States have websites that are conducive to citation searches. However, only searches on the websites of the U.S. Federal Reserve institutions provide a suitable sample from which to construct rankings. To remove the home-country bias, we exclude the citations of the host country when compiling the data. Results of a citation search on the U.S. Federal Reserve websites are reported on the right-hand side of Tables 7a and b. These results are very similar to those based on citations at the BIS, which seems to suggest that our conclusions based on BIS citations are somewhat robust.

As stated earlier, we expect a positive correlation between policy relevance and citations in the publications of an international policy-relevant organization. However, policy relevance

---

<sup>12</sup> A possible bias in the calculation of the number of citations per central bank researchers may be introduced by the fact that we do not exclude central bank documents that have been written by non-central bank researchers from the analysis. However, an informal examination of the results indicates that this does not affect our conclusions.

itself may also be a function of the current issues that dominate debates on the world economy, and the relative impact of each country's economic activity on world economic conditions. Furthermore, some institutions publish widely circulated policy documents that can garner more citations than working papers. Each U.S. Federal Reserve Bank, for instance, publishes its own economic review. Taken together, this can help explain the high number of citations for the United States, Europe, and Japan.

## **5. Determinants of Research Output**

In this section we analyze the factors that can help explain the rankings of research output. A myriad of variables are involved in the production functions of central banks, such as the quantity and quality of labour, computing resources, data availability, library resources, and support staff. It is difficult to measure the magnitude of all these ancillary resources over time for all central banks; they are beyond the scope of this paper. As a result, the productivity measures described herein are necessarily imperfect. Nevertheless, we do possess measures of the key factor of production, namely the number of researchers.

In addition to labour, we can examine the effects of some other measurable factors on published output:

- Production of working papers: Working papers are usually published to generate feedback on work in progress; does this translate into a higher volume of published work?
- Policy relevance of an institution's research output: Does producing policy-relevant research increase an institution's success in publishing its work?
- Collaboration with external partners: Does collaborating with external specialists increase an institution's amount of published research output?
- Size: Is there a negative relationship between the number of researchers in a central bank and their average product, as Eijffinger, de Haan, and Koedijk (2002) claim?

- Number of employees with a PhD: Does a higher ratio of PhDs to the number of researchers lead to higher productivity?

In the remainder of this section, we examine the impact of each of these variables on output. Because we have relatively few time-series observations at our disposal, it is difficult to test formal hypotheses related to causation; nevertheless, the simple correlations described should prove informative.

## 5.1 Labour

Tables 8a through d in Appendix A show results of the following regression for each country:

$$q_{k,t} = \alpha + \beta n_{k,t} + \varepsilon_t, \quad (6)$$

where  $q_{k,t}$  is as defined in Tables 5a through d; namely, the raw output of journal articles and various measures that correct for journal quality, co-authors, and page count for central bank  $k$  at time  $t$ . Meanwhile,  $n_{k,t}$  represents our two survey proxies for the number of researchers in the institution: the number of individuals who spend at least 50 per cent of their time conducting economic research (from Table 1a) and the number of PhDs in the institution (Table 1b). The parameter  $\beta$  therefore represents the marginal product of each institution's researchers. Alternatively, we can include both variables simultaneously, in which case the number of PhDs would represent a measure of the quality of the researchers, the motivation being that PhDs follow developments in the literature more closely, and are trained to perform original research.

Table 8a provides estimates of this simple equation for countries that have supplied the required data on inputs. Parameters are estimated for each country separately using ordinary least squares.<sup>13</sup> With few exceptions, we find that the marginal product of economic researchers at all institutions is positive using either input proxy. Given the relatively small (14 or fewer) number

---

<sup>13</sup> We also estimate the parameters using a panel data set; the estimates are qualitatively similar.

of observations in our sample, however, the parameter is significantly different from zero in slightly less than half of the institutions.

According to marginal product, the ECB is ranked highest, although its estimate is computed using only six annual observations. The San Francisco Fed is the only other institution with a marginal product greater than 2.0 using the 50 per cent definition, although it is statistically insignificant due to the lack of variation in the input data that it supplied. The institutions with the highest statistically significant measures of marginal output are the St. Louis Fed (1.72), Banque de France (1.20), Chicago Fed (1.07), and Bank of England (1.03). Using PhDs as research inputs, we find that the rankings are relatively unchanged for the top institutions, although notable movements are experienced by the Minneapolis Fed (going from 17th to 8th) and the Bank of England (6th to 20th).

The Bank of Canada places 22nd in terms of marginal product using the 50 per cent measure, and 18th in terms of the number of PhDs. The estimated parameters are relatively similar, however (0.18 and 0.31, respectively), indicating that the institution has to add about five researchers (or three PhDs) to boost its research output in academic journals by one paper per year.

When the output is adjusted for quality, we find that the San Francisco Fed and ECB tend to have the highest marginal product, followed by a number of other U.S. Federal Reserve banks.

It is interesting to note that for some central banks, such as the Chicago Fed, the average product per researcher (0.89 in Table 6a) is very similar to the corresponding estimated marginal product (1.07 in Table 8a). If labour is the only variable input, then equality of the marginal and average yearly product indicates that the average output has attained its maximum; i.e., hiring additional researchers at the Chicago Fed will not increase the average yearly output of published papers. Instead, average product increases would have to be attained through other means, such as higher capital investments (e.g., computing infrastructure), efficiency gains (e.g., a greater degree of research specialization), or more experienced researchers.

## 5.2 Working papers

To determine the extent of the link between working papers and published output, we plot in Figures 1 and 2 the relationships between total journal articles and working papers (Figure 1) and journal articles and working papers excluding external researchers (Figure 2). A central bank that publishes a high volume of papers written by external researchers will not normally be credited with a journal publication if the working paper is subsequently published in a journal, since the author's affiliation will not be with the central bank.

The 45-degree lines in Figures 1 and 2 help summarize the publication success of central banks: those institutions closest to the 45-degree line publish as many working papers as journal articles, those below it have fewer published journal articles per working paper, and those above it have more. We notice that only a handful of central banks lie above the line.

In addition, we plot two estimated regression lines based on the following equations:

$$q_k = \alpha + \beta_1 WP_k + \varepsilon_k, \text{ and} \quad (7)$$

$$q_k = \alpha + \beta_1 WP_k + \beta_2 WP_k^2 + \varepsilon_k, \quad (8)$$

where the variable  $q_k$  represents the number of journal articles published by the  $k$ th institution,  $WP_k$  is its working paper output, and  $\varepsilon_k$  is a random disturbance, where  $k = 1, \dots, 34$ . The squared working paper output is included as an additional regressor to test whether this relationship exhibits increasing, decreasing, or constant returns to scale.

The results show that working papers are a significant coincident indicator of published output, since there is, not surprisingly, a significant positive relationship between the two variables. In Table 9a, the correlations between working papers and various output measures are found to be in the vicinity of +0.50. What is perhaps somewhat surprising is that the relationship exhibits increasing returns to scale, indicating that increases in working paper output can yield a marginally higher number of published journal articles. However, this is largely attributed to the

BoG, which is an outlier; removing this institution from the sample yields a more linear relationship.

### **5.3 Policy relevance**

By developing separate measures for scientific quality and policy relevance, we do not mean to imply that a trade-off exists between the two. In fact, our expectation is that these two aspects of research quality would tend to reinforce each other. Papers with good scientific quality are likely to be more useful for policy-makers than lower-quality papers. Also, we expect that policy relevance is a plus for publications in top journals.

We assess these expectations by examining the relationship between our ranking of central banks based on the number of quality-adjusted publications in journals per researcher (right-hand column of Table 7a) with the ranking based on the number of citations of working papers in BIS publications per researcher (Table 8b). The result, shown in Figure 3, is consistent with our expectations. There is, in general, no trade-off between scientific quality and policy relevance. They are positively, but not perfectly, correlated.

The correlation between policy relevance and output is around +0.60 (Table 9a). This shows that there is a strong, positive, yet imperfect, relationship between the research output of central banks and its policy relevance.

### **5.4 Research collaboration**

Are institutions that collaborate extensively with external research partners more productive than those that collaborate less? Figure 4a plots the relationship between the rankings for collaboration ratios on working papers (shown in Table 3) and the average product of researchers (adjusted for the number of co-authors and the quality of journals); Figure 4b shows the relationship between the rankings of external collaborations and the number of citations by BIS publications per researcher.

We find that, in general, there is a very weak positive relationship between external collaboration and the number of journal publications per researcher. The correlations between collaboration and output measures (Table 9a) are just slightly above zero. This indicates that an effort on the part of central bankers to collaborate with external researchers will have a marginal impact on journal publications. However, such partnerships most likely result in the importing of fresh ideas, which cannot readily be proxied by our data. Furthermore, there does not seem to be a significant relationship between partnerships and the number of citations per researcher. Perhaps this should not be too surprising. Many of these partnerships are with academics and may lead to research papers that are not immediately useful to policy-makers.

Much more work needs to be done to fully understand the impact of research collaboration on research output. We would expect, in particular, that different types of partnerships bring different results. For instance, partnerships with academics might be of a different nature and have different implications for journal publications and policy relevance than partnerships with fellow central bank researchers. More data would be needed to explore this issue.

## **5.5 Size**

Eijffinger, de Haan, and Koedijk (2002) find that the average product of researchers in European central banks that have a small number of researchers tends to be superior to that of larger ones. Angelini (2003), however, argues that this conclusion reflects problems with the data used by Eijffinger, de Haan, and Koedijk. In their study of research output in European central banks, Jondeau and Pagès (2003) conclude that there is no significant relationship between average product and the number of researchers. We revisit this question with our broader set of data.

Our results are shown in Figures 5a and 5b. Figure 5a shows the relationship between the rankings for the number of researchers and number of journal publications (adjusted for quality and co-authors) per researcher, and Figure 5b shows the relationship between the number of researchers and number of BIS citations per researcher. Our conclusion based on these graphs is

that there is no significant relationship between size and average product in either of these cases. Correlation coefficients between size and different measures of average product (Table 9b) are also all close to zero. Robustness checks, in which we experimented with various input and output definitions, and from which we excluded certain central banks that seemed to be outliers, led to similar conclusions. This is in line with the conclusion of Jondeau and Pagès (2003) for Europe.

## 5.6 Number of PhDs

In section 5.1 we considered the number of PhDs as a quality adjustment in time-series regression. But can we find cross-sectional evidence of a positive relationship between the number of employees with a PhD and the number of journal publications or the number of BIS citations?

Figure 6a indicates that a high number of PhDs per number of researchers is positively correlated with the average number of publications per researcher. Figure 6b shows that this relationship is weaker when the number of BIS citations is used as the output measure. The correlations regarding the impact of PhDs on average product (Table 9b) are inconclusive.

## 6. Conclusion

Our first main contribution is to provide a systematic comparison of central bank research output based on publications in refereed journals by researchers from the central banks of Australia, Canada, Israel, Japan, New Zealand, the United States, and Western Europe. In particular, we report various rankings of central banks based on the number of articles published in refereed journals, and we use various approaches to adjust for the number of external co-authors and the quality of the journals. These rankings tend to be dominated by U.S. Federal Reserve banks. The Banca d'Italia, the Bank of England, and the European Central Bank also fare well in most cases. The Bank of Canada is near the middle of the rankings of 34 institutions, a result that is robust to various changes in assumptions and sample periods.

We also provide results on the number of journal publications per researcher based on compiled data on the number of researchers at each central bank. As before, U.S. Federal Reserve banks dominate these rankings. The ECB, the Bank of England, and the Sveriges Riksbank are also top-10 central banks. The Bank of Canada ranks lower by this measure.

Our second main contribution is the proposal of a new quantifiable indicator of policy relevance that can be used to assess the performance of central banks in this area. This indicator is based on the number of citations of central bank working papers in publications of the Bank for International Settlement (BIS) and the U.S. Federal Reserve System. The rankings of some central banks change noticeably when this measure of policy relevance is used. For instance, the Bank of Canada improves to ninth position in total BIS citations. Nevertheless, the data show that most central banks have similar rankings for policy relevance as they do for this measure. In other words, apart from a few exceptions, the same central banks tend to be found at the top and the bottom of both the ranking based on scientific quality and that based on policy relevance. Indeed, based on a preliminary investigation, we find that central banks that rank highly in quality-adjusted output also tend to rank highly in relevance. Thus, although some central banks do better by one measure than the other, there does not necessarily need to be a trade-off between research quality/quantity and relevance. On the contrary, they tend to reinforce each other.

Because there is a lack of detailed data on the factors that determine research output, we do not thoroughly examine the factors that affect the research performance of central banks. We do, however, find preliminary evidence of a very weak positive relationship between partnerships with external researchers and productivity in terms of the number of journal publications. More work would need to be done to determine the types of partnerships that yield the greatest output gains.

Another of our findings is that there is no robust relationship between the number of researchers in a central bank and average product measured either in terms of publications in refereed journals or BIS citations. This result is consistent with that of Jondeau and Pagès (2003) for European central banks, but it goes against the conclusion of Eijffinger, de Haan, and Koedijk (2002) that researchers in smaller central banks tend to be more productive.

We also find that there appears to be much diversity in central bank policies towards publishing working papers. While, in most central banks, researchers publish many more working papers than papers in refereed journals, a number of central banks show just the opposite trend, which suggests that they have very strict publication policies. Still, the number of working papers published seems to be a good contemporaneous indicator of journal publications for most central banks.

More work is needed to improve our understanding of the determinants of research output in central banks. This will require better and more detailed data to measure the number of researchers in central banks (although our main results seem robust to the three measures we consider), to capture factors such as the quality of capital and labour used in producing research, as well as the quality of research management.
